Recursive Algorithms for Estimation of Hidden Markov Models and Autoregressive Models With Markov Regime

Vikram Krishnamurthy, Senior Member, IEEE, and George Gang Yin, Senior Member, IEEE

Abstract—This paper is concerned with recursive algorithms for the estimation of hidden Markov models (HMMs) and autoregressive (AR) models under Markov regime. Convergence and rate of convergence results are derived. Acceleration of convergence by averaging of the iterates and the observations are treated. Finally, constant step-size tracking algorithms are presented and examined.

Index Terms—Convergence, hidden Markov estimation, rate of convergence, recursive estimation.

I. INTRODUCTION

MOTIVATED by many important applications in signal processing, speech recognition, communication systems, neural physiology, and environment modeling, in this paper, we consider recursive (online) estimation of the parameters of hidden Markov models (HMMs) and jump Markov autoregressive systems (also known as autoregressive processes with Markov regime), and develop stochastic approximation algorithms to carry out the estimation task. Our main effort is to prove the convergence and rate of convergence of these recursive estimation algorithms.

An HMM is a discrete-time stochastic process with two components \( \{X_n, Y_n\} \) such that \( \{X_n\} \) is a finite-state Markov chain and given \( \{X_n\}, \{Y_n\} \) is a sequence of conditionally independent random variables; the conditional distribution of \( Y_n \) depends only on \( X_n \). It is termed a hidden Markov chain since \( \{X_n\} \) is not observable and one has to rely on \( \{Y_n\} \) for any statistical inference task. Such models have been widely used in several areas including speech recognition and neurobiology; see [34] and the references therein.

In this paper, we consider both the standard HMMs and the more general autoregressive models under Markov regime, in which the autoregressive parameters switch in time according to the realization of a finite-state Markov chain, which are widely used in econometrics [15]–[17], statistical signal processing, and maneuvering target tracking (see [21] and the references therein). For such models, the distribution of the observables \( Y_n \) depend not only on \( X_n \), but also on \( Y_{n-1}, \ldots, Y_{n-d} \). Equivalently, \( Y_n \) is obtained by a regression on \( Y_{n-1}, \ldots, Y_{n-t} \), where \( d \) is the order of regression. The regression functions involved can be either linear or nonlinear. Our objective is to design and analyze the properties of recursive estimators for the parameters of such autoregressive (AR) processes with Markov regime.

Recently, Rydén [35], [36] proposed a batch recursive algorithm for parameter estimation of standard HMMs. His main idea is to use a stochastic approximation type algorithm on batches of data of length \( \geq 2 \). He proved the consistency by using the classical result of Kushner and Clark [22]; he also suggested an averaging approach in light of the recent development due to Polyak [33] and Ruppert [37] (see also [24] and [44]). LeGland and Mevel [29] have proved the consistency of a stochastic approximation algorithm for parameter estimation of HMMs called the recursive maximum-likelihood estimation (RMLE) algorithm. The RMLE algorithm in [29] has the advantage over the recursive-batch approach in [35] in that it is truly recursive. In Dey, Krishnamurthy, and Salmon-Legagneur [11] and Holst, Lindgren, Holst, and M. Thuvesholmen [19], stochastic approximation algorithms are presented for estimating the parameters of AR processes with Markov regime. However, these papers only provide simulation results of these algorithms and no proof of convergence or asymptotic normality is given. For the special case when the observations \( Y_n \) belong to a finite set (i.e., \( Y_n \) is a probabilistic function of a Markov chain), Arapostathis and Marcus [1] derived and analyzed recursive parameter estimation algorithms.

The main contributions of this paper are as follows.

1) We present the asymptotic analysis of the recursive maximum-likelihood estimation (RMLE) algorithm for estimating the parameters of HMMs and AR processes with Markov regime. We extend and generalize the results in [29] to AR models with Markov regime. Note that it is not possible to extend the batch recursive algorithm and the analysis in [35] to AR models with Markov regime.

is because the algorithm in [35] requires precise knowledge of the distribution of the state given past measurements at time instants \( m, 2m, 3m, \ldots \) where \( m \geq 2 \). In the RMLE algorithm presented in this paper, the initial distribution of the state (at time 0) given past observations is forgotten exponentially fast and hence is asymptotically negligible.

In Section III, we study the convergence and rate of convergence issues. Different from that of [29] and [35], we use state-of-the-art techniques in stochastic approximation (see Kushner and Yin [25]). As a result, the assumptions required are weaker and our formulation and results are more general than that of Rydén [35], [36] and LeGland and Mevel [29] because we are dealing with suitably scaled sequences of the iterates that are treated as stochastic processes rather than random variables. Our approach captures the dynamic evolution of the RMLE algorithm. As a consequence, using weak convergence methods we can analyze the tracking properties of the RMLE algorithms when the parameters are time varying (see Sections III and V for details).

2) In Section IV, a modified version of the RMLE algorithm that uses averaging in both the observations and the iterates for accelerating the convergence rate is given and analyzed.

3) In Section V, a constant step size version of the RMLE for tracking variations in the parameters of HMMs and AR processes with Markov regime is analyzed.

4) In Section VI, numerical examples are presented that illustrate the performance of the algorithms for both linear and nonlinear AR processes with Markov regime.

II. PROBLEM FORMULATION

A. Signal Model for HMM and AR Model With Markov Regime

Our signal model is defined on the probability space \( (\Omega, \mathcal{F}, P) \) as follows. Let \( \{X_k\}_{k=0}^{\infty} \) be a Markov chain with finite state space \( S = \{1, \ldots, r\} \), where \( r \) is fixed and known. For \( i, j = 1, \ldots, r \), the transition probabilities

\[
a_{ij} = P(X_n = j|X_{n-1} = i) = a_{ij}(\varphi)
\]

are functions of a parameter (vector) \( \varphi \) in a compact subset \( \Phi \) of an Euclidean space. Write \( A(\varphi) = (a_{ij}(\varphi)) \).

For the AR model with Markov regime, for \( n \geq 1 \), the observed real-valued process \( \{Y_k\}_{k=1}^{\infty} \) is defined by

\[
Y_n = g(Y_{n-1}, \ldots, Y_{n-d}; \varphi) = a_{ij}(\varphi)
\]

where \( \{g(\cdot; \theta); \theta \in \Theta\} \) is a family of real-valued functions on \( \mathbb{R}^{d+1} \), indexed by a parameter \( \theta \in \Theta \), \( \{\epsilon_n\} \) is a scalar sequence of independent and identically distributed (i.i.d.) random variables, \( d > 0 \) is a fixed and known integer, and \( \Theta \) is a Euclidean space with coordinate projections \( \theta_i; i = 1, 2, \ldots, r \), where \( \theta_i; \Phi \rightarrow \Theta \). We will discuss the distribution of the initial vector \( (Y_{-d+2}, \ldots, Y_0) \) below. Assume that at each time \( n \geq 0 \), each conditional distribution has a density with respect to (w.r.t.) the Lebesgue measure and denote this density by \( f(y_n|y_{n-1}, \ldots, y_{n-d}; \varphi) \). Let \( p \) be the dimension of the vector-valued parameter \( \varphi \). Other than Section V (where we consider tracking algorithms), we assume that there is a fixed \( \varphi^* \in \Phi \), which is the “true” parameter. Our objective is to design a recursive algorithm to estimate \( \varphi^* \).

In the HMM case, the observed real-valued process \( \{Y_k\}_{k=1}^{\infty} \) is defined by

\[
Y_n = g(\epsilon_n; \theta_{X_n}(\varphi))
\]

Clearly, it is a special case of the above AR model with \( d = 0 \).

Remark 2.1: For notational simplicity, we have assumed that \( \{\epsilon_k\} \) and \( \{Y_k\} \) are scalar-valued. The results straightforwardly generalize to vector-valued processes.

Notation: For notational convenience let

\[
Z_n \overset{\text{def}}{=} (Y_1, \ldots, Y_{n-d}).
\]

For the HMM case, \( d = 0 \), i.e., \( Z_n = Y_n \). In the subsequent development, we often use \( \kappa \) as a generic positive constant; its values may change for different usage. For a function \( h(\cdot) \), we use both \( \partial h(\varphi)/\partial \varphi \) and \( h_\varphi \) to denote the partial derivative with respect to \( \varphi \). For a vector or a matrix \( v, v' \) denotes its transpose. For an integer \( \ell \), let \( 1_\ell \) and \( O_\ell \), respectively, denote the \( \ell \)-dimensional column vector in which each element is \( 1 \) and \( 0 \), respectively.

Define the \( r \)-dimensional vector \( f(z_k; \varphi) \) and \( r \times r \) matrix \( F(z_k; \varphi) \) by

\[
f(z_k; \varphi) = [f_1(z_k; \varphi), \ldots, f_r(z_k; \varphi)]
\]

and

\[
F(z_k; \varphi) = \text{diag} [f_1(z_k; \varphi), \ldots, f_r(z_k; \varphi)]
\]

where

\[
f_i(z_k; \varphi) = f(y_{d+i}|y_{d+i-1}, \ldots, y_{d-i}; \theta_i(\varphi)),
\]

for some \( i = 1, \ldots, r \).

Let the conditional probability distribution of \( (Y_1, \ldots, Y_n) \) under \( P_\varphi \) be defined as

\[
P_n(y_1, \ldots, y_{n-d+1}, \ldots, y_{n-\ell}; \varphi) = P_\varphi(Y_n \in dy_{n-d+1}, \ldots, Y_1 \in dy_1|y_{d+i}, \ldots, y_{d-i})
\]

It is straightforward to show that [21]

\[
p(y_1, \ldots, y_{n-d+1}, \ldots, y_{n-\ell}; \varphi)
\]

\[
= \sum_{x_1=1}^{\text{dim} X_1} P_\varphi(X_1 = x_1|y_0, \ldots, y_{d+i}) \prod_{k=1}^n F(z_k; \varphi)A(\varphi)1_r
\]

The initial choice of \( P_\varphi(X_1 = x_1|y_0, \ldots, y_{d+i}) \) is unimportant since it does not affect the convergence analysis of the estimators—it may be taken as an arbitrary stochastic vector with positive entries. (The idea of substituting the true likelihood by the conditional likelihood given an initial sequence of observations goes back to Mann and Wald [31].)

Preliminary Assumptions: Throughout the rest of the paper, we assume the following conditions hold.

C1) The transition probability matrix \( A(\varphi^*) \) is positive, i.e.,

\[
a_{ij}(\varphi^*) \geq \hat{\epsilon} \quad \text{for all} \quad i, j \in \{1, 2, \ldots, r\}
\]

for some known \( \hat{\epsilon} > 0 \). The process

\[
\{Q_k\} = \{X_k; Z_k\} = \{X_k; Y_k, \ldots, Y_{k-d}\}
\]
is a geometrically ergodic Markov chain on the state space $S \times \mathbb{R}^{d+1}$ under $\varphi^*$. Let $\gamma$ denote the unique invariant measure of $\{Q_k\}$. 

**Remark 2.2.** For the HMM case, C1) can be relaxed to the condition that the transition probability matrix $A(\varphi^*)$ is aperiodic and irreducible, see [27].

For the AR model with Markov regime, in general, it is difficult to verify the geometric ergodicity of $Q_k$ for a given parameter $\varphi$. In [43], it is shown that for the model

$$Y_n = g(Y_{n-1}, \ldots, Y_{n-d}; \theta_{X_n}(\varphi)) + \epsilon_n$$

$Q_n$ is $V$-uniformly ergodic under the following conditions (note that $V$-uniform ergodicity implies geometric ergodicity).

i) **Sublinearity:** The $r$ mappings

$$[Y_{n-1}, \ldots, Y_{n-r}] \rightarrow g(Y_{n-1}, \ldots, Y_{n-d}; \theta_{i}(\varphi)),$$

are continuous and there are positive constants $\alpha_i$ and $\beta_i$ such that for some norm $| \cdot |$ on $\mathbb{R}^d$

$$|g(Y_{n-1}, \ldots, Y_{n-d}; \theta_{i}(\varphi))| \leq \alpha_i |[y_{n-1}, \ldots, y_{n-d}]| + \beta_i,$$

ii) For some $s \geq 1$, $E|\epsilon_n|^s < \infty$ for $s \geq 1$. The spectral radius $\rho(A_n) < 1$ where

$$A_n = \begin{bmatrix} \alpha_{n1} & \cdots & \alpha_{nr} \\ \vdots & \ddots & \vdots \\ \alpha_{nr1} & \cdots & \alpha_{nrr} \end{bmatrix},$$

iii) The marginal density of $\epsilon_n$ is positive.

The $V$-uniform ergodicity in turn implies that the following strong law of large numbers and central limit theorem holds for $Q_n$. Let $g: S \times \mathbb{R}^{d+1} \rightarrow \mathbb{R}$ denote a Borel measurable function with $\psi \in \mathcal{B}(s)$ where for $s > 1$, $(x, z) \in S \times \mathbb{R}^{d+1}$

$$\mathcal{B}(s) \overset{\text{def}}{=} \{ \psi: \psi(x, z) \leq \text{const}(1 + |z|^s) \}.$$

A) The following strong law of large numbers holds for $\psi \in \mathcal{B}(s)$:

$$\frac{1}{n} \sum_{k=1}^{n} \psi(X_k, Y_k) \rightarrow \gamma(\psi)$$

$$\overset{\text{def}}{=} \int_{S \times \mathbb{R}^{d+1}} \psi(x, z) d\gamma(x, z), \quad P_{\varphi^*} \text{ a.s.}$$

B) Define $\overline{\psi} = \psi - \gamma(\psi)$ and

$$\Sigma_\psi = E[\overline{\psi}(X_0, Z_0)] + \sum_{k=1}^{\infty} \Sigma_{\psi} = E[\overline{\psi}(X_0, Z_0)\overline{\psi}(X_0, Z_k)] + 2\sum_{k=1}^{\infty} E[\overline{\psi}(X_0, Z_0)\overline{\psi}(X_k, Z_k)].$$

Then for all $\psi \in \mathcal{B}(s/2)$, $\Sigma_\psi$ is well defined, nonnegative, and finite. If $\Sigma_\psi > 0$ then the following central limit theorem holds:

$$\frac{1}{\sqrt{n}} \sum_{k=1}^{n} [\psi(X_k, Z_k) - \gamma(\psi)] \rightarrow N(0, \Sigma_\psi) \text{ in distribution.}$$

For simplicity, sometimes we write $\psi(Q_k)$ in lieu of $\psi(X_k, Z_k)$.

C2) The mapping $\varphi \rightarrow A(\varphi)$ is twice differentiable with bounded first and second derivatives and Lipschitz continuous second derivative. For any $y_{k-1}, y_{k-1}, \ldots, y_{k-d+1}$, the mapping $\varphi \rightarrow f(z_n; \varphi)$ is three times differentiable. $f(z_n; \varphi)$ is continuous on $\mathbb{R}^{d+1}$ for each $\theta \in \Theta$.

C3) For each $i = 1, \ldots, r$, the conditional probability corresponding to the true parameter,

$$P_{\varphi^*}(X_k = i|Y_{k-1}, \ldots, Y_{k-d})$$

is continuous in $(y_{k-1}, \ldots, y_{k-d}) \in \mathbb{R}^d$ and is strictly positive w.p. 1.

**Remark 2.3:** Assumption C3) is a sufficient condition for identifiability of $\varphi^*$ for linear AR models with Markov regime when $\epsilon_n$ are normally distributed; see Remark 2.10 below.

**Example 2.4 (Linear AR Model With Markov Regime):** The fully parameterized linear case with Markov regime may be described by letting $A$ be the set of $r \times r$ stochastic matrices

$$\Theta = \{(b_1, \ldots, b_d, \sigma) \in \mathbb{R}^r \times (0, \infty) \}$$

and $\Phi \subset A \times \Theta$ with $a_i(b, \sigma)$ and $\theta_i(b, \sigma)$ being the coordinate projections, that is, $a_i(b, \sigma) = b_i$ and $\theta_i(b, \sigma) = \sigma_i$. The innovations $\{\epsilon_n\}$ may, for example, be a standard normal distribution, in which case $f(y_{k-1}, \ldots, y_{k-d}, \theta)$ is the density of the normal distribution with mean $b_1 y_{k-1} + \cdots + b_d y_{k-d}$ and variance $\sigma^2$. C1) holds under conditions ii) and iii) of Remark 2.2. C2) is satisfied if the marginal density of $\epsilon_n$ is continuous and has bounded derivatives w.r.t. $\varphi$. Finally, C3) holds if C1) holds and the marginal density of $\epsilon_n$ is positive, continuous, bounded, and has bounded derivatives w.r.t. $\varphi$; see the examples provided in [21] and also [6] and [7] for further details.

**Example 2.5 (HMM):** Using similar notation as in the above example, this is straightforwardly described with $A$ as above and $\Theta = \{(q_1, \sigma) \in \mathbb{R} \times (0, \infty) \}$$

$$g(q_1, \sigma; \theta) = q + \sigma \epsilon_n$$

where $q = \{q_1, \ldots, q_r\}$ and where $q_i$, $i = 1, \ldots, r$ are often referred to as the “state levels” of the HMM.

**B. HMM Prediction Filter**

In the sequel, our RMLE algorithm will be based on prediction filters for the state of the Markov chain. For all $n \geq 0$, define the $r$-dimensional column vector

$$u_n(\varphi) = [u_{n1}(\varphi), \ldots, u_{nr}(\varphi)]'$$

where

$$u_{ni}(\varphi) = P_{\varphi}(X_n = i|y_{n-1}, \ldots, y_{n-d+1})$$

denotes the predicted density of the Markov chain at time $n$ given observations until time $n-1$. It is straightforward to show that this predicted density can be recursively computed as

$$u_{n+1}(\varphi) = \frac{A(\varphi)F(z_n; \varphi)u_n(\varphi)}{f(z_n; \varphi)u_n(\varphi)} = T(z_n, u_n; \varphi) \quad (4)$$
initialized by some $u_0(\varphi)$. The above equation is commonly referred to as the HMM prediction filter, “forward” algorithm, or Baum’s equation [34]. Let $\mathcal{P}(S)$ denote the simplex in which $u_n(\varphi)$ resides.

Let $u_n^{(j)}(\varphi) = (\partial / \partial \varphi_j) u_n(\varphi)$ denote the partial derivative of $u_n(\varphi)$ with respect to the $j$th component of the $p$-dimensional parameter vector $\varphi$. Define the $r \times p$ matrix

$$
\Phi_n(\varphi) = \begin{pmatrix}
(u_n^{(1)}(\varphi), & \ldots, & u_n^{(p)}(\varphi))
\end{pmatrix}.
$$

Clearly, $u_n(\varphi)$ belongs to $\Xi$ defined by

$$
\Xi = \{ w \in \mathbb{R}^{r \times p} : 1^T w = 0^T_p \}.
$$

Differentiating $u_{n+1}(\varphi)$ with respect to $\varphi_j$ yields

$$
u_{n+1}^{(j)}(\varphi) = \frac{\partial u_{n+1}(\varphi)}{\partial \varphi_j} = R_1 \left( z_n, u_n(\varphi), \varphi \right) u_n^{(j)}(\varphi) + R_2 \left( z_n, u_n(\varphi), \varphi \right)
$$

where

$$
R_1 \left( z_n, u_n(\varphi), \varphi \right) = A'(\varphi) \left[ I - \frac{F(z_n; \varphi) u_n(\varphi) 1^T_z}{F'(z_n; \varphi) u_n(\varphi)} \right] F(z_n; \varphi) u_n(\varphi),
$$

$$
R_2 \left( z_n, u_n(\varphi), \varphi \right) = A'(\varphi) \left[ I - \frac{F(z_n; \varphi) u_n(\varphi) 1^T_z}{F'(z_n; \varphi) u_n(\varphi)} \right] \frac{\partial F(z_n; \varphi)}{\partial \varphi_j} u_n(\varphi) + \frac{\partial A'(\varphi)}{\partial \varphi_j} F(z_n; \varphi) u_n(\varphi).
$$

Under the measure $P_{\varphi}$, the extended Markov chain

$$
\{ X_n, Z_n, u_n(\varphi), w_n(\varphi) \}
$$

is proved in [27]. We briefly summarize their results here. Define for any $i \geq 0$ and $s = 0, 1, 2, 3$

$$
\delta^s(z) = \sup_{\varphi \in \mathcal{P} \Theta} \max_{i = 0, 1, \ldots, p} \min_{i = 0, 1, \ldots, p} \frac{\partial A^s_i}{\partial \varphi_j} F(z_n; \varphi) u_n(\varphi),
$$

$$
\Delta^i(z) = \sup_{\varphi \in \mathcal{P} \Theta} \min_{i = 0, 1, \ldots, p} \max_{i = 0, 1, \ldots, p} \frac{\partial A^s_i}{\partial \varphi_j} F(z_n; \varphi) u_n(\varphi),
$$

$$
\Gamma_i = \sup_{\varphi \in \mathcal{P} \Theta} \max_{i = 0, 1, \ldots, p} \int_\mathbb{R} \left[ \delta^i(z) f_i(z; \varphi) \right] f_i(z; \varphi)' dz.
$$

where for $\varphi'$ denotes the true parameter. It is shown in [27] that for a locally Lipschitz function $h_i$ the following holds. A sufficient condition for geometric ergodicity of

$$
\{ X_n, Z_n, u_n(\varphi), w_n(\varphi) \}
$$

is that C1 holds, and the mapping $u \mapsto R_2^{(j)}(z, u, \varphi)$ is locally Lipschitz for any $z \in \mathbb{R}^{d+1}$ [27, Assumption C] and $\Delta^{(0)}_i$ is finite. A sufficient condition for $u \mapsto R_2^{(j)}(z, u, \varphi)$ to be locally Lipschitz is $\Delta^{(0)}_i$ is finite (see [27, Example 4.3]). Note that if the noise density $f_i(z; \varphi)$, $i \in S$, is Gaussian, then $\Gamma_i, \Gamma'_{i}, \Gamma_\ast_{i}$, and $\Gamma_{i,\ast}$ are finite for $i \geq 0$.

**Remark 2.7 (AR Model With Markov Regime):** The above conditions on $\Delta_i$ do not directly apply to AR models with Markov regime. In [13], weaker sufficient conditions are given for the exponential forgetting of $u_n(\varphi)$. We summarize this result and outline how it can be used to show geometric ergodicity of $\{ X_n, Z_n, u_n(\varphi), w_n(\varphi) \}$.

As in [13, Assumption A1], assume in addition to C1) that for $y \in \mathbb{R}, \xi \in \mathbb{R}^d, z = (y, \xi)$

$$
0 < \min_{\varphi \in \mathcal{P} \Theta} \inf_i f_i(z; \varphi) \quad \text{and} \quad \max_{\varphi \in \mathcal{P} \Theta} \sup_i f_i(z; \varphi) < \infty.
$$
Suppose $u_n(\varphi)$ and $\hat{u}_n(\varphi)$ are predictors with initial conditions $u_0(\varphi)$ and $\hat{u}_0(\varphi)$, respectively. Then it is proved in [13, Corollary 1] that
\[
|u_n(\varphi) - \hat{u}_n(\varphi)| < \rho^n, \quad \rho \leq 1 - \inf_{\varphi \in \Phi} \min_{i,j} u_{ij}(\varphi) \sup_{\varphi \in \Phi} \max_{i,j} \hat{u}_{ij}(\varphi), \quad (10)
\]
Compared with the results of [27], $\rho$ is observation independent. As a consequence, starting from (10) one can obtain the geometric ergodicity of $(X_n, Z_n, u_n(\varphi), \hat{u}_n(\varphi))$ along the lines of [27, Secs. 3 and 5] as follows.

- By exactly the same steps as the proof of [27, Proposition 3.8], one can establish that for any locally Lipschitz function $h = (h)^i, i \in S$
\[
\int_{\mathbb{R}} \cdots \int_{\mathbb{R}} \left| h^{i_{n+1}}(z_{n+1}, u_n(\varphi)) - h^{i_{n+1}}(z_{n+1}, \hat{u}_n(\varphi)) \right| \cdot f_{i_{n}}(z_{n}; \varphi^*) \cdots f_{i_{n+1}}(z_{n+1}; \varphi^*) dy_{n} \cdots dy_{n+1} \leq \text{Lip}(h) \int_{\mathbb{R}} \cdots \int_{\mathbb{R}} \left| u_n(\varphi) - \hat{u}_n(\varphi) \right| \cdot f_{i_{n}}(z_{n}; \varphi^*) \cdots f_{i_{n+1}}(z_{n+1}; \varphi^*) dy_{n} \cdots dy_{n+1}, \quad (11)
\]
In [27], the exponent $\delta(y)$ for the exponential forgetting of $\left| u_n(\varphi) - \hat{u}_n(\varphi) \right|$ depends on the observations—hence integrability conditions such that $\Delta_k < \infty$ are required. In contrast with the exponential forgetting (10), it follows from (11) that [27, Proposition 3.8] holds.

- The proof of geometric ergodicity of $(X_n, Z_n, u_n(\varphi))$ then follows along the lines of [27, Theorem 3.6], but the argument is much simpler because $\rho$ is observation independent.

As in [27], assume that $R_0(\varphi, u(\varphi), \varphi)$ is Lipschitz continuous in $u$. Assuming C1 and (10), the geometric ergodicity of $(X_n, Z_n, u_n(\varphi), \hat{u}_n(\varphi))$ follows along the same lines as [27, Secs. 4 and 5]. In particular, for $z = (y, \xi)$ where $\xi \in \mathbb{R}^d$, define $\bar{\delta}(0)(z) = \max_{\varphi} \sup_{\varphi} \| \partial_x f_i(z; \varphi) \|$ and $\bar{\delta}(1)(z) = \max_{\varphi} \sup_{\varphi} \| \partial_x f_i(z; \varphi) \|$. Then the integrability conditions
\[
\max_{i} \sup_{\varphi} \int_{\mathbb{R}} \left| \bar{\delta}(0)(z) \right|^2 f_i(z; \varphi) dy < \infty
\]
and
\[
\max_{i} \sup_{\varphi} \int_{\mathbb{R}} \left| \bar{\delta}(1)(z) \right|^2 f_i(z; \varphi) dy < \infty
\]
for all $\xi \in \mathbb{R}^d$ are sufficient for geometric ergodicity of $(X_n, Z_n, u_n(\varphi), \hat{u}_n(\varphi))$.

### C. Kullback–Leibler Information

The conditional log-likelihood function (suitably normalized) based on the observations $y_{d+1}, \ldots, y_n$ is
\[
l_n(\varphi) = \frac{1}{n+1} \log p_n(y_h, \ldots, y_{d+1}, \ldots, y_0; \varphi).
\]

It is straightforward to show that the conditional log-likelihood can be expressed as the sum of terms involving the observations and the observed state (prediction filter) as follows:
\[
l_n(\varphi) = \frac{1}{n+1} \sum_{k=0}^{n} \log \left[ f'(z_k; \varphi) u_k(\varphi) \right]. \quad (12)
\]

For the HMM case, under assumptions C1 and C4, [27, Example 3.4] shows that the $\log f'(z_k; \varphi) u_k(\varphi)$ is locally Lipschitz if $\Delta_k(0)$ and $\Gamma_k(1)$ are finite. This and the geometric ergodicity yield that the following strong law of large numbers holds.

**Proposition 2.8 (HMM Case):** Under assumptions C1, C2, and C4, if $\Delta_k(0)$ and $\Gamma_k(1)$ are finite, then for any $\varphi \in \Phi$ there exists a finite $l(\varphi)$ such that
\[
l_n(\varphi) \rightarrow l(\varphi), \quad P_{\varphi} \text{ w.p. } 1 \text{ as } n \rightarrow \infty
\]

where
\[
l(\varphi) = \int_{\mathbb{R}^d \times \mathcal{P}(S)} \log \left[ f'(z; \varphi) u_n(\varphi) \right] \nu_{\varphi}(dz, du)
\]
and $\nu_{\varphi}$ denotes the marginal density of the invariant measure $\mu_{\varphi}$ defined on $\mathbb{R}^d \times \mathcal{P}(S)$.

For the AR case with Markov regime the following strong law of large numbers holds—see [13, Proposition 1] for proof.

**Proposition 2.9 (AR With Markov Regime):** Under C1, C2, and C4, with $z = (y, \xi)$ if $\sup_{\varphi} \sup_{\theta, y} f_i(z; \varphi) < \infty$ and $E_{\varphi}(\log \sup_{\varphi} f_i(z; \varphi)) < \infty$ for all $i \in S$ then for any $\varphi \in \Phi$ there exists a finite $l(\varphi)$ such that
\[
l_n(\varphi) \rightarrow l(\varphi), \quad P_{\varphi} \text{ w.p. } 1 \text{ as } n \rightarrow \infty
\]

where
\[
l(\varphi) = \int_{\mathbb{R}^d+1 \times \mathcal{P}(S)} \log \left[ f'(z; \varphi) u_n(\varphi) \right] \nu_{\varphi}(dz, du)
\]
and $\nu_{\varphi}$ denotes the marginal density of the invariant measure $\mu_{\varphi}$ defined on $\mathbb{R}^{d+1} \times \mathcal{P}(S)$.

Recall that $\varphi^*$ is the true parameter that we are seeking. Under C1–C4, define for any $\varphi \in \Phi$ the Kullback–Leibler information as
\[
K(\varphi) = - \left[ l(\varphi) - l(\varphi^*) \right] \geq 0.
\]

We have proved in [21] that $\varphi^*$ belongs to the set $L_{\text{ML}}$ of global minima of $K(\varphi)$
\[
L_{\text{ML}} = \arg \min_{\varphi \in \Phi} K(\varphi). \quad (13)
\]

In addition, the ML estimator (MLE)
\[
\hat{\varphi}_{\text{ML}} = \arg \max_{\varphi \in \Phi} l_n(\varphi)
\]
is strongly consistent.

**Remark 2.10 (Identifiability in Linear AR Case):** Consider the linear AR process with Markov regime of Example 2.4. Assume $e_k$ is normally distributed. Assume that the true model vectors $(h_0, \ldots, h_n, \sigma^2)$ are distinct, so that for each $n$, there exists a point $(y_{h-1}, \ldots, y_{h-d}) \in \mathbb{R}^d$ such that $(h_0, \ldots, h_n, \sigma^2)$ is distinct. Then using C3, it is proved in [21, Example 3] that $\varphi^*$ is uniquely identifiable, in the sense that $K(\varphi) = 0$ implies that $\varphi = \varphi^*$ up to a permutation of indices.

### D. RMLE Algorithm

To estimate $\varphi^*$, one can search for the minima of the Kullback–Leibler divergence $K(\varphi)$. Assuming the function $K(\cdot)$ is
sufficiently smooth, the parameter estimation problem is converted to finding the zeros of \( (\partial / \partial \varphi)K(\cdot) \). In this paper, we use a recursive algorithm of stochastic approximation type to carry out the task. Recalling that the symbol \( \prime \) denotes transpose and differentiating the terms within the summation in (9) with respect to \( \varphi_l \) yields the \( p \)-dimensional "incremental score vector"

\[
S(\hat{Y}_n; \varphi) = \left( S^{(1)}(\hat{Y}_n; \varphi), \ldots, S^{(p)}(\hat{Y}_n; \varphi) \right)'
\]

with

\[
S^{(l)}(\hat{Y}_n; \varphi) = \frac{f'(z_n; \varphi) u_n^{(l)}(\varphi)}{f(z_n; \varphi) u_n(\varphi)} + \left[ (\partial / \partial \varphi_l) f'(z_n; \varphi) \right] u_n(\varphi)
\]

where

\[
\hat{Y}_n \equiv (Z_n, u_n(\varphi), u_n(\varphi))
\]

with \( u_n \) and \( u_n(\varphi) \) defined by (4) and (5), respectively. The RMLE algorithm takes the form

\[
\varphi_{n+1} = \Pi_G \left( \varphi_n + \varepsilon_n S(\hat{Y}_n; \varphi_n) \right).
\]

In (13), \( \{ \varepsilon_n \} \) is a sequence of step sizes satisfying \( 0 \leq \varepsilon_n \to 0 \) and \( \sum_{n=0}^{\infty} \varepsilon_n = \infty \). \( G \) is a convex and compact set, and \( \Pi_G \) denotes the projection of the estimate to the set \( G \). More precise conditions will be given later. Note that in (13), following the usual approach in stochastic approximation, we have collected \( (Z_n, u_n, u_n(\varphi)) \) in \( \hat{Y}_n \). This enables us to treat \( \hat{Y}_n \) as a noise process. Our task to follow is to analyze the asymptotic properties of (13). Moreover, we also examine its variant algorithms.

III. ASYMPTOTIC PROPERTIES

The objective of this section is to analyze the convergence and rate of convergence of the RMLE algorithm proposed in the previous section. In what follows, we use the results in [25] whenever possible with appropriate references noted. For the convergence analysis, we use the ordinary differential equation (ODE) approach that relates the discrete-time iterations of the RMLE algorithm to an ODE. For rate of convergence, we present a weak convergence analysis to examine the dependence of the estimation error \( \varphi_n - \varphi^* \) on the step size \( \varepsilon_n \). We answer the question for what real number \( c_\varepsilon \), \( \varepsilon_n^0 (\varphi_n - \varphi^*) \) converges to a nontrivial limit.

Note that our formulation and results are more general than that of Rydén [35], [36] because we are dealing with suitably scaled sequences of the iterates that are treated as stochastic processes rather than random variables. Our approach captures the dynamic evolution of the RMLE algorithm. As a consequence, we can analyze the tracking properties of the RMLE algorithms when the parameters are time varying, which is done in Section V.

A. Preliminaries

First rewrite the first equation in (13) as

\[
\varphi_{n+1} = \varphi_n + \varepsilon_n S(\hat{Y}_n; \varphi_n) + \varepsilon_n M_n
\]

where \( M_n \) is the projection or correction term, i.e., it is the vector of shortest Euclidean length needed to bring \( \varphi_n + \varepsilon_n S(\hat{Y}_n; \varphi_n) \) back to the constraint set \( G \) if it ever escapes from \( G \) (see [25, p. 89] for more discussion). For future use, denote by \( F_n \) the \( \sigma \) algebra generated by \( \{ \varphi_0, \hat{Y}_j, j < n \} \), and let \( E_n \) denote the conditional expectation with respect to \( F_n \).

Constraint Set: Let \( q_i(\cdot), i = 1, \ldots, p \), be continuously differentiable real-valued functions on \( \mathbb{R}^p \). Without loss of generality, let \( (\partial / \partial \varphi) q_i(\varphi) \neq 0 \) if \( q_i(\varphi) = 0 \). Let the constraint set be

\[
G = \{ \varphi : q_i(\varphi) \leq 0, i = 1, \ldots, p \}
\]

and assume it is connected, compact, and nonempty. A constraint \( q_i(\cdot) \) is active at \( \varphi \) if \( q_i(\varphi) = 0 \). Define \( A(\varphi) \), the set of indexes of the active constraints at \( \varphi \), by \( A(\varphi) = \{ i : q_i(\varphi) = 0 \} \). Define \( C(\varphi) \) to be the convex cone generated by the set of outward normals \( \{ \psi : \psi = (\partial / \partial \varphi) q_i(\varphi), i \in A(\varphi) \} \). Suppose for each \( \varphi \), \( \{ (\partial / \partial \varphi) q_i(\varphi), i \in A(\varphi), A(\varphi) \neq \emptyset \} \) is linearly independent. If \( q_i(\varphi) \neq 0 \) for all \( i \), then \( C(\varphi) \) contains only the zero element.

To prove the convergence of the algorithm, we use the ODE approach (see Kushner and Clark [22]); the following development follows the framework setup in [25]). Take a piecewise-constant interpolation of \( \varphi_n \) as follows. Define \( t_0 = 0 \) and

\[
t_n = \sum_{i=0}^{n-1} \varepsilon_i, \quad m(t) = \begin{cases} \text{unique } \varepsilon_n; \ t_n \leq t < t_{n+1}, & \text{for } t \geq 0 \\ 0, & \text{for } t < 0 \end{cases}
\]

Let

\[
\varphi^0(t) = \begin{cases} \varphi_0, & \text{for } t \leq 0 \\ \varphi_n, & \text{for } t_n \leq t < t_{n+1}, & \text{for } t \geq 0 \end{cases}
\]

Define the sequence of shifted process \( \varphi^0(\cdot) \) by

\[
\varphi^0(t) = \varphi^0(t_n + t), \quad \text{for } t \in (-\infty, \infty)
\]

Define \( M^0(\cdot) \) and \( M^n(\cdot) \) by

\[
M^0(t) = \left\{ \begin{array}{ll} \sum_{i=0}^{n(t)-1} \varepsilon_i M_i, & \text{for } t \geq 0 \\ 0, & \text{for } t < 0 \end{array} \right.
\]

and

\[
M^n(t) = \left\{ \begin{array}{ll} M^0(t_n + t) - M^0(t), & \text{for } t \geq 0 \\ -\sum_{i=m(t_n+\varepsilon_i)}^{n(t)-1} \varepsilon_i M_i, & \text{for } t < 0 \end{array} \right.
\]

Using such interpolations, one then shows that \( \{ \varphi^0(\cdot), M^n(\cdot) \} \) is equicontinuous in the extended sense [25, p. 73] and uniformly bounded. By the Ascoli–Arzelà theorem, we can extract a convergent subsequence such that its limit satisfies a projected ODE, which is one whose dynamics are projected onto the constraint set \( G \).

Projected ODE: Consider the projected ODE

\[
\dot{\varphi} = H(\varphi) + \tilde{m}, \quad \varphi(0) = \varphi_0, \quad \tilde{m} \in -C(\varphi)
\]

where \( H(\varphi) = (\partial / \partial \varphi) K(\varphi) \), and \( \tilde{m}(\cdot) \) is the projection or constraint term. The term \( \tilde{m}(\cdot) \) is the minimum force needed to keep \( \varphi(\cdot) \in G \). Let \( L_G = \{ \varphi : \varphi \text{ be a limit point of } (15), \varphi_0 \notin G \} \), and \( \tilde{L}_G = \{ \varphi \in G : H(\varphi) + \tilde{m} = 0 \} \). The points in \( \tilde{L}_G \) are termed stationary points. When \( \varphi \in G^0 \), the interior of \( G \), the stationary condition is \( (\partial / \partial \varphi) K(\varphi) = H(\varphi) = 0 \), and when \( \varphi \notin \partial G \), the boundary of \( G \), \( H(\varphi) \in C(\varphi) \). For more discussion on projected ODE, see [25, Sec. 4.3] for details. A set
\( \mathcal{A} \subset G \) is locally asymptotically stable in the sense of Liapunov for (15), if for each \( \delta > 0 \), there is a \( \delta_1 > 0 \) such that all trajectories starting in \( N_{\delta_1}(\mathcal{A}) \) never leave \( N_{\delta}(\mathcal{A}) \) and ultimately stay in \( N_{\delta_1}(\mathcal{A}) \), where \( N_{\delta}(\mathcal{A}) \) denotes an \( \eta \) neighborhood of \( \mathcal{A} \).

**B. Convergence**

Assume the following conditions are satisfied.

A1) Conditions C1)–C4) hold.

A2) For each \( \varphi \in G \), \( \{S(\hat{Y}_j; \varphi)\} \) is uniformly integrable, \( \mathbb{E}[S(\hat{Y}_j; \varphi)] = H(\varphi) = (\partial / \partial \varphi)K(\varphi) \), \( H(\cdot) \) is continuous, and \( S(\hat{Y}_j; \cdot) \) is continuous for each \( \hat{Y} \). There exist nonnegative measurable functions \( \hat{p}(\cdot) \) and \( \hat{r}(\cdot) \) such that \( \hat{r}(\cdot) \) is bounded on bounded \( \varphi \), set, and

\[
\left| S(\hat{Y}_j; \varphi) - S(\hat{Y}_i; \psi) \right| \leq \hat{r}(\varphi - \psi) \hat{r}(\hat{Y}_j)
\]

such that \( \hat{r}(\varphi) \to 0 \) as \( \varphi \to 0 \) and

\[
P \left( \limsup \sup_n \sum_{i=a}^{m(t_n+s)} e_i \hat{Y}_i < \infty \right) = 1,
\]

for some \( s > 0 \).

In the above, the expectation is taken w.r.t. the \( \varphi \)-parameterized stationary distribution.

A3) Suppose that \( L_\mathcal{A}^1 \) is a subset of \( L_\mathcal{C} \) and \( L_{\text{ML}} \) is locally asymptotically stable. For any initial condition \( \varphi_0 \not\in L_\mathcal{A}^1 \), the trajectories of (15) go to \( L_{\text{ML}} \).

**Remark 3.1:** For the HMM case, A2) holds if the marginal density of \( e_k \) is Gaussian. A sufficient condition for the uniform integrability and Lipschitz continuity in A2) is that \( \Delta^{(4)}_2, \Gamma_2 \), and \( \Gamma_2 \) in (8) are finite; see [29].

Consider the AR case with Markov regime: A2) is easily verifiable for the AR(1) linear case (i.e., \( d = 1 \) in (3))

\[
Y_{k+1} = -b_{Y_{k+1}} \hat{Y}_k + \epsilon_k \quad \text{where} \quad |b_2| < 1, \quad i = 1, 2, \ldots, r.
\]

Suppose \( \{e_k\} \) is a sequence of i.i.d. Gaussian random variables with zero mean and finite variance \( \sigma^2 \). It is easily seen that for each \( (Y_k, Y_{k-1}) \in \mathbb{R}^2 \), \( f(\cdot, \cdot) \) is continuously differentiable w.r.t. \( \theta \) with bounded derivatives and hence it is Lipschitz continuous. It is also clear that the Lipschitz constant depends on \( (Y_k, Y_{k-1}) \). Thus, by using (4), (5), and (11), A2) is verified. Higher order linear AR models with Markov regime (i.e., \( d > 1 \)) can be treated in a similar way with more complex notation.

Regarding the uniform integrability, suppose that for each \( \varphi \in G \), \( \mathbb{E}[|S(\hat{Y}_j; \varphi)|^4] < \infty \) for some \( \Delta > 0 \). Then the uniform integrability is verified. If \( \{S(\hat{Y}_j; \varphi)\} \) is bounded by an integrable random variable \( \hat{U} \) in the sense

\[
P(\{S(\hat{Y}_j; \varphi) \geq \alpha \}) \leq P(\{\hat{U} \geq \alpha \})
\]

then \( \{S(\hat{Y}_j; \varphi)\} \) is also uniformly integrable. More specifically, if \( h \) satisfies the condition (6) with \( K(h^i, z) \) verifies

\[
\sup_{x \in \mathbb{R}} \int_{\mathbb{R}^{d+1}} [K(h^i, z)]^z f_h(x^*, \varphi) \, dx < \infty.
\]

Then by noting that \( B_{\mathbb{E}_{(n+1)}^2} = \mathbb{B}_{\mathbb{E}_{(n+1)}^2} = e_{n+1} B_{\mathbb{E}_{(n+1)}^2} \)

\[
\hat{c}_{n+1}(\varphi) - \hat{c}_{n}(\varphi) = \hat{c}_{n+1}(\varphi) - \hat{c}_{n}(\varphi) + (\delta \hat{c}_{n+1}(\varphi) - \delta \hat{c}_{n}(\varphi)) = e_n(\hat{S}(\hat{Y}_i; \varphi) - H(\varphi)) + \sum_{i=1}^{n+1} \epsilon_i B_{(n+1)} \mathbb{E}_{(n+1)}^2(\hat{S}(\hat{Y}_i; \varphi) - H(\varphi))
\]

\[
- \sum_{i=1}^{n+1} \epsilon_i B_{(n+1)} \mathbb{E}_{(n+1)}^2(\hat{S}(\hat{Y}_i; \varphi) - H(\varphi)) = \delta \hat{N}_n(\varphi) + e_{n+1} E_n \delta \hat{c}_{n+1}(\varphi),
\]

**Lemma 3.2:** Under the conditions A1) and A2), for each \( \varphi \), each \( \mu > 0 \), and some \( T > 0 \)

\[
\lim_{n \to \infty} P \left\{ \sup_{j \geq n} \max_{0 \leq t \leq T} \left| m(jT+t) - 1 \right| \sum_{i=m(jT)}^{m(jT+t)-1} e_i (\hat{S}(\hat{Y}_i; \varphi) - H(\varphi)) \geq \mu \right\} = 0.
\]

**Remark 3.3:** To prove the consistency of stochastic approximation algorithms, a crucial step is to verify that condition (17) holds. Such conditions were first brought in by Kushner and Clark in [22]; it is summarized in the current form and referred to as “asymptotic rate of change” in [25, Secs. 5.3 and 6.1]. These conditions appear to be close to the minimal requirement needed, and have been proved to be necessary and sufficient condition in certain cases [42]. To verify this condition, we use the idea of perturbed state or perturbed test function methods. Note that our conditions are weaker than that of [35]. Only finite first moment is needed.

**Proof of Lemma 3.2:** We use a discounted perturbation. The use of perturbed test function for stochastic approximation was initiated by Kushner, and the discounted modification was suggested in Solo and Kong [39]. For future use, define

\[
B_{\mathbb{E}_{(n+1)}^2} = \left\{ \prod_{k=1}^{n} \left( 1 - \epsilon_k \right), \quad i \geq n \right\}
\]

For each \( \varphi \), define \( v_n(\varphi) \) as

\[
v_n(\varphi) = 0
\]

\[
v_{n+1}(\varphi) = v_n(\varphi) + \epsilon_n(\hat{S}(\hat{Y}_n; \varphi) - H(\varphi)), \quad n \geq 0
\]

\[
\delta v_n(\varphi) = \sum_{i=n}^{\infty} e_i B_{(n+1)} \mathbb{E}_{(n+1)}^2(\hat{S}(\hat{Y}_i; \varphi) - H(\varphi))
\]

\[
\delta v_n(\varphi) = \sum_{i=n}^{\infty} e_i B_{(n+1)} \mathbb{E}_{(n+1)}^2(\hat{S}(\hat{Y}_i; \varphi) - H(\varphi))
\]

Then by noting that \( B_{(n+1)} = B_{(n+1)} \mathbb{E}_{(n+1)}^2 \)

\[
\hat{c}_{n+1}(\varphi) - \hat{c}_{n}(\varphi) = \hat{c}_{n+1}(\varphi) - \hat{c}_{n}(\varphi) + (\delta \hat{c}_{n+1}(\varphi) - \delta \hat{c}_{n}(\varphi)) = e_n(\hat{S}(\hat{Y}_i; \varphi) - H(\varphi)) + \sum_{i=n}^{\infty} e_i B_{(n+1)} \mathbb{E}_{(n+1)}^2(\hat{S}(\hat{Y}_i; \varphi) - H(\varphi))
\]

\[
- \sum_{i=n}^{\infty} e_i B_{(n+1)} \mathbb{E}_{(n+1)}^2(\hat{S}(\hat{Y}_i; \varphi) - H(\varphi)) = \delta \hat{N}_n(\varphi) + e_{n+1} E_n \delta \hat{c}_{n+1}(\varphi),
\]
Note that by telescoping
\[
\sup_n \sum_{i=0}^{\infty} \varepsilon_i B_i(n+1) = \sup_n \sum_{i=0}^{\infty} (B_{i+1} - B_i(n+1)) < \infty.
\]
It yields that
\[
\sup_n \sum_{i=0}^{\infty} \varepsilon_i B_i(n+1) = \sup_n \sum_{i=0}^{\infty} \frac{\varepsilon_i - \varepsilon_{i+1}}{\varepsilon_i} \varepsilon_i B_i(n+1)
\]
\[
+ \sup_n \sum_{i=0}^{\infty} \varepsilon_i B_i(n+1) < \infty.
\]
Therefore,
\[
\sum_{i=0}^{\infty} \varepsilon_i B_i \rightarrow 0 \text{ as } n \rightarrow \infty.
\]
Owing to A2)
\[
\sum_{i=0}^{\infty} \varepsilon_i B_i < \infty \quad \text{and} \quad \sum_{i=0}^{\infty} \varepsilon_i B_i \mathbb{E} |S(\tilde{Y}; \varphi)| < \infty
\]
so
\[
\sum_{i=0}^{\infty} \varepsilon_i B_i S(\tilde{Y}; \varphi) \text{ converges w.p. } 1
\]
and
\[
\sum_{i=0}^{\infty} \varepsilon_i B_i(n+1) \mathbb{E} S(\tilde{Y}; \varphi) \rightarrow 0 \text{ w.p. } 1.
\]
Similarly,
\[
\sum_{i=0}^{\infty} \varepsilon_i B_i \mathbb{E} \left| S(\tilde{Y}; \varphi) - H(\varphi) \right| < \infty
\]
\[
\sum_{i=0}^{\infty} \varepsilon_i B_i S(\tilde{Y}; \varphi) - H(\varphi) \rightarrow 0 \text{ w.p. } 1
\]
and
\[
\sum_{i=0}^{\infty} \varepsilon_i B_i(n+1) \mathbb{E} (E_{n+1} S(\tilde{Y}; \varphi) - H(\varphi)) \rightarrow 0 \text{ w.p. } 1.
\]
Consequently, \( \delta \mathbb{E}_n(\varphi) \rightarrow 0 \text{ w.p. } 1 \) as \( n \rightarrow \infty \). Likewise,
\[
\sum_{i=n}^{\infty} \varepsilon_i B_i(n+2) \mathbb{E} (E_{n+1} S(\tilde{Y}; \varphi) - H(\varphi))
\]
\[
+ \sum_{i=n}^{\infty} \varepsilon_i B_i(n+2) \mathbb{E} (E_{n+1} S(\tilde{Y}; \varphi) - H(\varphi)) < \infty
\]
and hence \( \delta N_n(\varphi) \rightarrow 0 \text{ w.p. } 1 \) as \( n \rightarrow \infty \). As a result,
\[
\varepsilon_{n+1} E_{n+1} \delta \mathbb{E}_n+1(\varphi) \rightarrow 0 \text{ w.p. } 1
\]
and
\[
\tilde{v}_{n+1}(\varphi) - \tilde{v}_n(\varphi) \rightarrow 0 \text{ w.p. } 1.
\]
Therefore, the asymptotic rate of change of
\[
\sum_{t=0}^{m(t)-1} \varepsilon_t \left( S(\tilde{Y}; \varphi) - H(\varphi) \right) \text{ is w.p. } 0 \text{ as } t \rightarrow \infty.
\]
The proof of the lemma is concluded. \( \square \)

**Theorem 3.4:** Assume conditions A1) and A2). There is a null set \( \tilde{N} \) such that for all \( \omega \notin \tilde{N} \), \( \{\varphi^\omega(\omega, \cdot), M^\omega(\omega, \cdot)\} \) is equicontinuous (in the extended sense as in [25, p. 73]). Let \( (\varphi(\omega, \cdot), M(\omega, \cdot)) \) denote the limit of some convergent subsequence. Then the pair satisfies the projected ODE (15), and \( \{\varphi_n\} \) converges to an invariant set of the ODE in \( G \).

Assume A3). Then the limit points are in \( L^1 \cup \tilde{A}_G \) w.p. 1. If, in particular, \( L^1 \cup \tilde{A}_G = \{\varphi^*\} \), and \( \varphi_n \) visit \( L^1 \cup \tilde{A}_G \) infinitely often w.p. 1, then \( \varphi_n \rightarrow \varphi^* \) w.p. 1.

**Proof:** The proof follows from Lemma 3.2, [25, Theorems 6.1.1 and 5.2.2]. \( \square \)

**Remark 3.5:** In view of [22, Theorem 5.3.1], the set of stationary points of (15) is the set of Kuhn–Tucker points

\[ \mathcal{KT} = \left\{ \varphi^* : \text{there exist } \lambda_i \geq 0 \text{ such that} \right\} \]

\[ -H(\varphi) + \sum_{\varphi(\cdot, \cdot) = 0} \frac{\partial H(\varphi)}{\partial \varphi} = 0 \]

As observed in [21], for linear AR processes with Markov regime, the only global minima of \( K(\varphi) \) are \( \varphi^* \) and possibly also parameters equal to \( \varphi^* \) up to a permutation of states.

**C. Rate of Convergence**

Since our main concern here is the convergence rate, we assume that \( \varphi^* \in G^0 \), the interior of \( G \), and that \( \varphi_n \) converges to \( \varphi^* \) w.p. 1. Suppose the following conditions hold.

A4) \( (\varepsilon_n/\varepsilon_{n+1})^{1/2} = 1 + \mu_n \) where either
a) \( \mu_n = 1/(2n) + o(\varepsilon_n) \)

b) \( \mu_n = o(\varepsilon_n) \).

A5) For each \( \varphi \in G, \mathbb{E} \left[ S(\tilde{Y}; \varphi) \right]^{2+\Delta} < \infty \) for some \( \Delta > 0 \) and \( \{\partial/\partial \varphi S(\tilde{Y}; \varphi)\} \) is uniformly integrable.

A6) \( \varphi_n \rightarrow \varphi^* \) w.p. 1 and \( \{\varphi_n - \varphi^*\}/\sqrt{\varepsilon_n} \) is tight.

A7) a) \( S(\tilde{Y}; \cdot) \) has continuous partial derivatives for each \( \tilde{Y} \), \( H(\cdot) \) is continuously differentiable, and \( H_{\varphi}(\varphi^*) = (\partial/\partial \varphi)H(\varphi^*) \) is Hurwitz (i.e., all of its eigenvalues have negative real parts).

b) If A4) a) holds (in this case, \( \varepsilon_n = O(1/n) \)), then \( H_{\varphi}(\varphi^*) + I/2 \) is also Hurwitz.

A8) Denote \( S_i = S(\tilde{Y}_i; \varphi^*) \). For \( i \leq j \leq n \), define \( r_n(i-j) = E_{n}(S_{i-j}) \) and \( \tilde{R}(i-j) = E_{n}(\tilde{S}_{i-j}) \) such that

\[ \sum_{i \geq j} R(i-j) < \infty. \]

**Remark 3.6:** Assumption A4) is a condition on the step size. Strictly speaking, it is not an assumption since the step size is at our disposal. Typical examples include \( \varepsilon_n = A/n \) for some \( A > 0 \), which satisfies a) in A4), and \( \varepsilon_n = A_0/n^\gamma \) for some \( 0 < \gamma < 1 \), which satisfies b) in A4). It also covers a wide variety of other cases.

In the HMM case, a sufficient condition for A5) to hold is that \( \Sigma_2, \Delta_2(1), \Delta_2(2), \text{ and } \Delta_2(3) \) are finite, see [29, Assumption B']. These hold for example, when \( \{\varepsilon_n\} \) is a sequence of Gaussian noises.

Condition A5) can be verified for linear Gaussian autoregressive processes with Markov regime. Consider the AR(1) case

\[ \mathcal{Y}_{n+1} = -\beta X_{n+1} + Y_n + \varepsilon_n, \]

where the meaning and conditions of
the parameters are as in Remark 3.1. In view of the discussion in Remark 2.4, it is easily seen that
\[
\frac{\partial f(z_n; \theta)}{\partial \theta_k} = -\frac{y_n - 1}{\sqrt{2\pi\sigma^2}} (y_n + b_1y_{n-1}) \exp \left( -\frac{(y_n + b_1y_{n-1})^2}{2\sigma^2} \right)
\]
and
\[
\frac{\partial f(z_n; \theta)}{\partial \sigma} = -\frac{1}{\sqrt{2\pi\sigma^4}} (y_n + b_1y_{n-1})^2 \exp \left( -\frac{(y_n + b_1y_{n-1})^2}{2\sigma^2} \right).
\]
Since a normal distribution has finite moments of any order
\[
E \left| \frac{\partial f(z_n; \theta)}{\partial \theta_k} \right|^{2+\Delta} < \infty \quad \text{and} \quad E \left| \frac{\partial f(z_n; \theta)}{\partial \sigma} \right|^{2+\Delta} < \infty.
\]
In view of (4), (5), and (11), \( E [S(Y_n, \phi)]^{2+\Delta} < \infty \). Higher order linear AR models with Markov regime (i.e., \( d > 1 \)) can be treated in a similar way with more complex notation. The moment condition is needed in functional central limit theorem; see [5, 14]. If the noise \( Y_n \) has moment generating function, then all moments are finite. In the Gaussian case, it is characterized by the first two moments.

Again, we can supply sufficient conditions ensuring the uniform integrability. For example, as in the discussion in Remark 3.1, in view of (6), if \( \{Z_n\} \) is uniformly integrable and \( K(h^*, z) \) verifies
\[
\max_{\eta z \leq 1} \int_{R^{d+1}} \left[ K(h^*, z) \right]^{(2+\Delta)/(1+\Delta)} f(z, \phi^*) d\zeta < \infty \tag{21}
\]
in lieu of (16), the uniform integrability can be verified by use of Hölder inequality.

Condition A7 ensures the limit stochastic differential equation (22) is asymptotically stable. That is, \( R \) is a stable matrix (see the definition of \( R \) in Theorem 3.9). Such a stability is necessary for the rate of convergence study; see the discussion after Theorem 3.9, in particular, the asymptotic covariance representation (23).

The smoothness condition of \( H(\phi) \) is used for convenience only. Aiming to obtaining local limit result, the only requirement is that \( H(\phi) \) is locally linearizable by a stable matrix. The smoothness assumption can be replaced by
\[
H(\phi) = \tilde{H}(\phi - \phi^*) + o(|\phi - \phi^*|) \tag{22}
\]
where \( \tilde{H} \) is a stable matrix (the real parts of its eigenvalues are all negative). Under (19), all the subsequent development goes through with \( H_{\phi}(\phi^*) \) replaced by \( \tilde{H} \). Note also that the form of (19) is a standard condition used in stochastic approximation. Finally, [13] provides a central limit theorem for the score vector.

Condition A8 simply says that the correlation decays sufficiently fast. It is shown in [27, Example 5.2] that for the HMM case, if \( \Delta(0) \) defined in (8) is finite, then \( S(\tilde{Y}; \phi) \) is locally Lipschitz. As a result, \( S(\tilde{Y}^*; \phi) \) is geometrically ergodic. For the AR case if \( S(\tilde{Y}; \phi) \) is locally Lipschitz in \( \tilde{Y} \), i.e., (6) holds then \( S(\tilde{Y}^*; \phi) \) is geometrically ergodic and satisfies (8). For the linear Gaussian AR case with Markov regime, A8 is easily verifiable; see also the remarks about A2). The condition we propose models that of a mixing process. As indicated in [5, p. 168], for example, the mixing condition is satisfied for a Markov chain that verifies a Doebblin condition, has one ergodic class, and is aperiodic; the condition is also satisfied for certain functions of mixing processes.

The tightness of the rescaled sequence can be verified by using a perturbed Liapunov function method. Sufficient conditions can be given. In fact, in Section IV, we will prove such an assertion. We assume this condition here for simplicity.

By the smoothness of \( S(\cdot) \), a Taylor expansion leads to
\[
S(\tilde{Y}; \phi) = S(\tilde{Y}; \phi^*) + \frac{\partial}{\partial \phi} S(\tilde{Y}; \phi^*)(\phi - \phi^*)
\]
and
\[
\varphi_{n+1} = \varphi_n + \epsilon_n S(\tilde{Y}_n; \phi^*) + \epsilon_n \frac{\partial S(\tilde{Y}_n; \phi^*)}{\partial \phi}(\varphi_n - \phi^*)
\]
\[
+ \epsilon_n \int_0^1 \frac{\partial}{\partial \phi} S(\tilde{Y}_n + s(\varphi_n - \phi^*); \phi^*) ds(\varphi_n - \phi^*) + \epsilon_n \rho_n \tag{23}
\]
where \( \rho_n = o(\|U_n\|) \) in probability due by use of the Taylor expansion and the uniform integrability of \( (\partial/\partial \phi) S(\tilde{Y}_n; \phi) \). Now define
\[
W^n(t) = \sum_{i=n}^{m(t_n+)+1} \sqrt{\varepsilon_i} S_i; \quad t \geq 0
\]
\[
= -\sum_{i=m(t_n+)+1}^{n-1} \sqrt{\varepsilon_i} S_i; \quad t < 0
\]
where \( S_i = S(\tilde{Y}_i; \phi^*) - H(\phi^*), \) Let \( W^n(t) \) be the piecewise-constant interpolation of \( \{U_i, i \geq n\} \) on \([0, \infty)\).

**Lemma 3.7:** Under A1, A5), and A7), for each \( \mu \)
\[
\frac{1}{n} \sum_{j=\mu}^{\mu+n} S(\tilde{Y}_j; \phi^*) \to 0 \quad \text{w.p. 1, as } n \to \infty
\]
\[
\frac{1}{n} \sum_{j=\mu}^{\mu+n} \frac{\partial}{\partial \phi} S(\tilde{Y}_j; \phi^*) \to \frac{\partial}{\partial \phi} H(\phi^*) \quad \text{w.p. 1, as } n \to \infty.
\]

**Proof:** Note
\[
S(\tilde{Y}_j; \phi^*) = S(g(\theta^*, \tilde{Y}_{j-1}, \ldots, \tilde{Y}_j-1, e_j); \phi^*)
\]
By A1), \( \{Q_k\} \) is stationary and ergodic. Thus
\[
\frac{1}{n} \sum_{j=\mu}^{\mu+n} S(\tilde{Y}_j; \phi^*)
\]
The second assertion is also proved. 

Since \( \{ (\partial/\partial \varphi) S(\hat{Y}_j; \varphi) \} \) is uniformly integrable, by A5, the dominated convergence theorem then yields

\[
\frac{1}{n}\sum_{j=1}^{n} \frac{\partial}{\partial \varphi} S(\hat{Y}_j; \varphi^*) \to E \frac{\partial}{\partial \varphi} S(\hat{Y}_j; \varphi^*) = \frac{\partial}{\partial \varphi} H(\varphi^*) \quad \text{w.p. } 1.
\]

The second assertion is also proved. 

\( \square \)

Lemma 3.8: Under A1, A5, and A8, \( W_n(\cdot) \) converges weakly to a Brownian motion \( W(\cdot) \) with covariance \( \Sigma \) where

\[
\Sigma = E S_1 S_1' + \sum_{i=2}^{\infty} E S_i S_i' + \sum_{i=1}^{\infty} E S_i S_1' .
\]  

(24)

Proof: Note that

\[
E_{m(t_n+t)} | W_n(t+s) - W_n(t) |^2 \leq \kappa \sum_{j=m(t_n+t)} \sum_{i=1}^{\infty} \sqrt{\varepsilon_i} \sqrt{\varepsilon_j} E_{m(t_n+t)} S_i S_j
\]

\[
\leq \kappa \sum_{j=m(t_n+t)} \sum_{i=1}^{\infty} \varepsilon_j \varepsilon_i E_{m(t_n+t)} S_i S_j .
\]

Since

\[
E \sum_{i=1}^{\infty} E_{m(t_n+t)} S_i S_j \leq \sum_{i=1}^{\infty} R(i-j) \leq \kappa
\]

by virtue of A8, and

\[
m(t_n+t+s+1) \geq \sum_{j=m(t_n+t)} \varepsilon_j
\]

\( = O(s) \lim_{s \to 0} \limsup_n E E_{m(t_n+t)} | W_n(t+s) - W_n(t) |^2 = 0.\)

It follows from the tightness criterion (see [14], [23]), \( W_n(\cdot) \) is tight in \( D^{r+1}(0, \infty) \times D^{r+1}(\infty, \infty) \).

By Prohorov's theorem (see [5], [14]), we can extract a convergent subsequence. Do so and for simplicity, still index it by \( n \) with limit denoted by \( W(\cdot) \). For any bounded and continuous function \( h(\cdot), \) any integer \( k, \) any real numbers \( t, s \geq 0, \) and any \( t_j \leq t_j \leq t_j \) for \( j \leq k, \) we have that \( W_n(t_j) \) are \( \mathcal{F}_{m(t_n+t)} \) measurable and

\[
E h(W_n(t_j), j \leq k)(W_n(t+s) - W_n(t)) = E h(W_n(t_j), j \leq k) E_{m(t_n+t)} \sum_{i=m(t_n+t)} \sqrt{\varepsilon_i} S_i \to 0,
\]

as \( n \to \infty. \)

Owing to A5, \( \{S_i \}^2 \) is uniformly integrable. This together with the estimate above and the weak convergence implies

\[
E h(W(t_j), j \leq k)(W(t+s) - W(t)) = 0.
\]

Thus, \( W(\cdot) \) is a continuous martingale. Next consider its quadratic variation. We have

\[
E h(W_n(t_j), j \leq k)(W_n(t+s) - W_n(t)) \to E h(W(t_j), j \leq k) \Sigma s,
\]

as \( n \to \infty \)

where \( \Sigma \) is given by (21). Therefore, the limit \( W(\cdot) \) is a Brownian motion with covariance \( \Sigma \) as desired. Since the limit does not depend on the chosen subsequence, the lemma follows.

\( \square \)

To carry out the weak convergence analysis, an appropriate way is to truncate the dynamics of \( U^M(\cdot) \) and works with a truncated version \( U^{M,M}(\cdot) \) with \( M < \infty \) first. One then proceeds with proving the tightness and weak convergence of \( U^{M,M}(\cdot) \) and finally passing the limit to \( M \to \infty \) (see [23], [25] for references). Using the lemmas above, carrying out the details as in [25, Sections 10.1 and 10.2], we establish the following theorem.

Theorem 3.9: A1), and A4–A8). Then the sequence \( \{U^M(\cdot), W_n(\cdot)\} \) converges weakly in \( D^{r+1}(0, \infty) \times D^{r+1}(\infty, \infty) \)

to \( (U(\cdot), W(\cdot)) \), where \( W(\cdot) \) is a Brownian motion with covariance \( \Sigma \) and \( U(\cdot) \) is stationary such that

\[
dU = RU dt + dW
\]

(25)

where

\[
R = \begin{cases}
H_{\varphi}(\varphi^*), & \text{under A4 a)} \\
H_{\varphi}(\varphi^*) + I/2, & \text{under A4 b)}
\end{cases}
\]

Remark 3.10: In the sense of equivalence of probability distribution on \( D^{r+1}(0, \infty) \times D^{r+1}(\infty, \infty) \), we can write

\[
U(t) = \int_{-\infty}^t \exp(R(t-s)) dW(s)
\]

which is the stationary solution of (22). The reason for using \( D^{r+1}(\infty, \infty) \) is mainly because it allows us to write \( U(t) \) as in the above representation involving the entire past of the Brownian motion (see [25, Ch. 10] for further details).

Note that the above theorem effectively gives the rate of convergence result. That is, it gives the order of the scaling, namely, \( \sqrt{\varepsilon_n} \) and the asymptotic covariance. To further illustrate, rewrite (22) as

\[
dU = RU dt + \Sigma^{1/2} d\tilde{w}
\]

where \( \tilde{w}(\cdot) \) is a standard Brownian motion. The asymptotic covariance \( \Sigma_0 \) of the underlying process is a solution of the algebraic Liapunov equation

\[
R \Sigma_0 + \Sigma_0 R = -\Sigma,
\]

and has the following representation:

\[
\Sigma_0 = \int_0^t \exp(Rt) \Sigma \exp(R^t) dt.
\]

(26)

An immediate consequence is that as \( n \to \infty \)

\[
(\varphi_n - \varphi^*)/\sqrt{\varepsilon_n} \sim N(0, \Sigma_0)
\]

i.e., it is asymptotically normal with asymptotic covariance \( \Sigma_0 \). The result we have obtained is more general than that of [35]. First it is from a stochastic process point of view, and focuses on trajectories of the normalized sequence of the estimation errors. Second, it covers a broad range of step-size sequences.

Note that the step sizes have a major influence on the rate of convergence. This is clearly seen from the representations of \( R \) corresponding to assumptions A4 a) and A4 b), respectively; see also the related work [45] for the rate results for global optimization algorithms.
IV. CONVERGENCE ACCELERATION BY ITERATE AND OBSERVATION AVERAGING

For designing recursive algorithms, to improve the asymptotic efficiency is an important issue. The effort for analyzing stochastic approximation type of algorithm in this direction can be traced back to that of Chung [9]. Suppose that \( \varepsilon_n = 1/n^\gamma \) for some \( 0 < \gamma \leq 1 \) and that there is a unique asymptotic stable point \( \varphi^* \) in the interior of \( G \). Then \( (\varphi_n - \varphi^*)/\varepsilon_n \) is asymptotically normal. Among the \( \gamma \)'s given above, the best one is \( \gamma = 1 \) as far as the scaling factor is concerned. If one uses \( \varepsilon_n = 1/n \), then it can be demonstrated that the best choice of \( \Gamma \) is the inverse of the gradient of \( H(\cdot) \) evaluated at \( \varphi = \varphi^* \). This quantity is normally not available. One could construct a sequence of estimates, but the amount of computation is often infeasible, especially for many applications we encounter in the hidden Markov estimation. In addition, from a computation point of view, one may not wish to use a rapidly decreasing sequence of step sizes decaying as \( \varepsilon_n = O(1/n^\gamma) \) since this produces a very slow movement in the initial stage.

Taking these into consideration, an approach of using iterate averaging was suggested in Polyak [33] and Ruppert [37] independently. The idea is that after using a larger than \( O(1/n) \) step-size sequence in an initial estimation, one takes an average of the resulting iterates yielding asymptotic optimality. Their results were extended in Yin [44] for mixing type of signals, and generalized further in Kushner and Yang [24] together with an explanation on why the approach works well using a two-time scale interpretation. Meanwhile, Bather [2] suggested another approach that requires the use of not only the iterate averaging but also the averaging in the observation. Schwabe [38] examined further this approach. The convergence and asymptotic optimality were obtained in Yin and Yin [46] for correlated noise.

Treating the HMM estimation problem, Rydén [35] suggested to adopt the iterate averaging to improve the efficiency of the estimation scheme. In this paper, motivated by the work [2], we use an averaging approach with averaging in both iterates and observations. This approach seems to have a smoothing effect that is useful for the initial stage of approximation. Henceforth, for notational simplicity, we take the initial time of the iteration to be \( n = 1 \) and consider an algorithm of the form

\[
\varphi_{n+1} = \Pi_G\left(\varphi_n + \varepsilon_n n S_n\right)
\]

\[
\bar{\varphi}_{n+1} = \bar{\varphi}_n - \frac{1}{n+1} \bar{\varphi}_n + \frac{n+1}{n+1} \bar{\varphi}_{n+1},
\]

\[
\bar{S}_{n+1} = \bar{S}_n - \frac{1}{n+1} \bar{S}_n + \frac{n+1}{n+1} S_{n+1}
\]

where \( G \) is the same constraint set as given before. Note that the algorithm above has the two-time scale interpretation; see [24] (see also [4] and [25]). Rewrite the first equation above as

\[
\varphi_{n+1} = \varphi_n + \varepsilon_n n \bar{S}_n + \varepsilon_n M_n
\]

where \( M_n \) is the projection term. We proceed to analyze the above algorithm.

A. Convergence

In what follows, we take \( \varepsilon_n = 1/n^\gamma \) with \( 1/2 < \gamma < 1 \). More general step size sequences can be treated. The particular form of the step sizes are selected to simplify the argument and notation in the proof. Note that strictly speaking, (25) is not a recursion for \( \varphi_n \) in the usual stochastic approximation setting. First, let us rewrite it in a more convenient form.

In view of the definition in (25), taking difference of \( \varphi_{n+1} - \varphi_n \) and using

\[
\varphi_n - \varphi_{n-1} = \frac{1}{n} \varphi_n - \frac{1}{n} \bar{\varphi}_{n-1}
\]

we arrive at

\[
\varphi_{n+1} = \varphi_n + \frac{1}{n} S(\bar{Y}_n; \varphi_n) + \frac{1 - \gamma}{(n - 1)^\gamma} \frac{1}{n} \sum_{i=1}^{n-1} S(Y_i; \varphi_i) + \frac{1}{n} \rho_n \sum_{i=1}^{n-1} S(Y_i; \varphi_i) + \frac{1}{n} M_n,
\]

for \( n > 1 \) (29)

where \( \rho_n = O(1/n^2) \).

In [46], dealing with an unconstrained algorithm, we used a recursive formulation similar as above, and examined an auxiliary sequence that is known to converge. Then we compared the difference of the estimates with that of the auxiliary process, and upper-bounded their difference by means of Gronwall’s inequality. Here we use a somewhat different approach and treat (26) directly. Define \( \varphi_n(\cdot) \) and \( M_n(\cdot) \) the same as before. We have the following result.

**Theorem 4.1:** Under the conditions of Theorem 3.4, its conclusions continue to hold for (24).

**Proof:** Define \( F_n(t) \), \( \bar{F}_n(t) \), and \( \bar{F}_n(t) \) on \( t \in (-\infty, \infty) \) as the piecewise-constant interpolations of the second, the third, and the fourth terms on the right-hand side of the equality sign of (26); for \( t \geq 0 \), these terms are

\[
F_n(t) = \sum_{i=1}^{m(t_n+t-1)} \frac{1}{\bar{y}_i} S(\bar{Y}_i; \varphi_i)
\]

\[
\bar{F}_n(t) = \sum_{i=1}^{m(t_n+t-1)} \frac{1 - \gamma}{(i-1)^\gamma} \frac{1}{\bar{y}_i} \sum_{j=1}^{i-1} S(\bar{Y}_j; \varphi_j)
\]

\[
\bar{G}_n(t) = \sum_{i=1}^{m(t_n+t-1)} \frac{1}{(i-1)^\gamma} \rho_i \sum_{j=1}^{i-1} S(\bar{Y}_j; \varphi_j).
\]

Then we have

\[
\varphi_n(t) = \varphi_n + F_n(t) + \bar{G}_n(t) + \bar{F}_n(t) + M_n(t).
\]

By applying Lemma 3.2 to each of the functions above, we conclude that there is a null set \( \bar{N} \) such that for all \( \omega \notin \bar{N} \), \( \{\varphi_n(\omega, \cdot), M_n(\omega, \cdot)\} \) is equicontinuous (in the extended sense [25, p. 73]). Extract a convergent subsequence with index \( n_k \) and limit \( (\varphi(\omega, \cdot), M(\omega, \cdot)) \). We proceed to characterize the limit.

Work with a fixed sample path for \( \omega \notin \bar{N} \), and suppress the \( \omega \) dependence. For \( t \geq 0 \), with given \( \delta > 0 \), split \( F_n(t) \) into three terms

\[
F_n^{(1)}(t) = \sum_{j=1}^{m(t_n+t-1)} \sum_{i=m(t_n+j \delta+\varepsilon)}^{m(t_n+j \delta+\varepsilon+1)} \frac{1}{\bar{y}_i} H(\varphi(j \delta))
\]

\[
F_n^{(2)}(t) = \sum_{j=1}^{m(t_n+t-1)} \sum_{i=m(t_n+j \delta+\varepsilon)}^{m(t_n+j \delta+\varepsilon+1)} \frac{1}{\bar{y}_i} H(\varphi(j \delta))
\]

\[
F_n^{(3)}(t) = \sum_{j=1}^{m(t_n+t-1)} \sum_{i=m(t_n+j \delta+\varepsilon)}^{m(t_n+j \delta+\varepsilon+1)} \frac{1}{\bar{y}_i} H(\varphi(j \delta))
\]
\[ F_{2}^{m}(t) = \sum_{j=1}^{[t/d] - 1} \sum_{i=m(t_{0} + j + \delta)-1}^{m(t_{0} + j + \delta + \delta)-1} \frac{1}{i} \left[ S(\hat{Y}_{i}; \varphi_{j}) - S(\hat{Y}_{i}; \varphi(j)) \right] \]
\[ = \sum_{i=m(t_{0} + j + \delta + \delta)-1}^{m(t_{0} + j + \delta + \delta)-1} \frac{1}{i} \left[ S(\hat{Y}_{i}; \varphi(j)) - H(\varphi(j)) \right] \]
where \([b]\) denotes the integer part of \(b \in \mathbb{R}\). As \(\delta \to 0\), it is easy to see that
\[ F_{2}^{m}(t) \to \int_{0}^{t} H(\varphi(s)) \, ds. \]

For \( F_{2}^{m}(t) \), by A2, we have
\[ |F_{2}^{m}(t)| \leq \sup_{m(t_{0} + j + \delta + \delta)-1}^{m(t_{0} + j + \delta + \delta)-1} \frac{1}{i} \left| S(\hat{Y}_{i}; \varphi) - H(\varphi) \right| \to 0 \text{ w.p. 1.} \]

What we need to do now is to approximate \( \varphi(j) \) by some fixed \( \varphi \). To do so, for given \( \eta > 0 \), let \( \{B_{l}^{\eta}; l \leq l_{\eta}\} \) be a finite collection of disjoint sets with diameter smaller than \( \eta \), and \( \varphi_{l}^{\eta} \in B_{l}^{\eta} \)
for \( l \leq l_{\eta} \), and \( \bigcup_{l=1}^{l_{\eta}} B_{l}^{\eta} = G \). Write
\[ \sum_{i=m(t_{0} + j + \delta + \delta)-1}^{m(t_{0} + j + \delta + \delta)-1} \frac{1}{i} \left[ S(\hat{Y}_{i}; \varphi(j)) - H(\varphi(j)) \right] = \sum_{l=1}^{l_{\eta}} I_{\{\varphi(j) \in B_{l}^{\eta}\}} \frac{1}{i} \left[ S(\hat{Y}_{i}; \varphi_{l}^{\eta}) - H(\varphi_{l}^{\eta}) \right]. \]

For fixed \( \eta > 0 \), as \( k \to \infty \), the above term goes to 0 by Lemma 3.2. It then follows that the limit is zero as \( k \to \infty \) and then \( \eta \to 0 \).

Using the same technique, we can show \( \hat{F}_{2}^{m}(t) \to 0 \) and \( \hat{F}_{2}^{m}(t) \to 0 \) as \( k \to \infty \). The desired limit then follows.

**B. Asymptotic Optimality**

To proceed, we demonstrate the averaging algorithm is asymptotically efficient. In what follows, assume that \( \varphi_{n} \to \varphi^{*} \) w.p. 1, and \( \varphi^{*} \in G^{*} \). Thus, the boundary of \( G \), namely, \( \partial G \), is reached only a finite number of times. Without loss of generality, we drop the reflection term \( M_{n} \) and assume the iterates are bounded in \( G^{*} \).

**Estimate of \( E[\varphi_{n} - \varphi^{*}]^{2} \)**: The estimate is of stability type. We use the perturbed Lyapunov function method that is to add a small perturbation to a Lyapunov function. The purpose of the addition of the small perturbation is to result in desired cancellations. Define the perturbations \( \hat{P}_{n} \) and \( \hat{P}_{n}^{*} \) by
\[ \hat{P}_{n} = \sum_{i=n}^{\infty} \frac{1}{i} B_{i(n+1)} E_{n} S(\hat{Y}_{i}; \varphi^{*}) \]
\[ \hat{P}_{n}^{*} = \sum_{i=n}^{\infty} \frac{1}{i} B_{i(n+1)} E_{n} \left[ S_{\varphi}(\hat{Y}_{i}; \varphi^{*}) - H_{\varphi}(\varphi^{*}) \right] \]
\[ \hat{P}_{n} = \sum_{i=n}^{\infty} \frac{1}{i} B_{i(n+1)} E_{n} \hat{\xi}_{i} \]
respectively, where
\[ \hat{\xi}_{n} = \zeta_{n} \left( 1 + O\left( \frac{1}{n} \right) \right) \]
and
\[ \zeta_{n} = \frac{1}{n} \sum_{i=1}^{n} S(\hat{Y}_{i}; \varphi_{i}) + \rho_{n} \sum_{i=1}^{n} S(\hat{Y}_{i}; \varphi_{i}). \]

Their use will be clear from the subsequent development.

**Theorem 4.2**: Assume that A1, A2, and A5–A8) hold, for sufficiently small \( \eta > 0 \)
\[ E \left| S(\hat{Y}_{n}; \varphi_{n}) \right| I_{||\varphi_{n} - \varphi^{*}|| \leq \eta} < \infty \]
and
\[ \sup_{n} E \left| \hat{P}_{n} \right| \left( 1 + |S(\hat{Y}_{n}; \varphi_{n})| \right) I_{||\varphi_{n} - \varphi^{*}|| \leq \eta} \leq \frac{K}{n^{\gamma}} \]
\[ \sup_{n} E \left| \hat{P}_{n} \right| \left( 1 + |S(\hat{Y}_{n}; \varphi_{n})| + |S(\hat{Y}_{n}; \varphi_{n})|^{2} \right) \]
\[ \cdot I_{||\varphi_{n} - \varphi^{*}|| \leq \eta} \leq \frac{K}{n^{\gamma}} \]
\[ \sup_{n} E \left| \hat{P}_{n} \right| \left( 1 + |\xi_{n}| + |\xi_{n}^{2}| \right) I_{||\varphi_{n} - \varphi^{*}|| \leq \eta} \leq \frac{K}{n^{n}}. \]

Then \( E[\varphi_{n} - \varphi^{*}]^{2} = O(1/n^{\gamma}) \) and \( E[\varphi_{n} - \varphi^{*}]^{2} = O(1/n^{1/2}) \) for \( n \) large enough.

**Proof**: Use a Taylor expansion
\[ S(\hat{Y}; \varphi) = S(\hat{Y}; \varphi^{*}) + S_{\varphi}(\hat{Y}; \varphi^{*}) (\varphi - \varphi^{*}) + \pi(\varphi, \hat{Y}; \varphi^{*}) \]
where
\[ \pi(\varphi, \hat{Y}) = \int_{0}^{1} S_{\varphi}(\hat{Y}; \varphi^{*} + s(\varphi - \varphi^{*})) \, ds. \]

Rewrite (26) as
\[ \varphi_{n+1} = \varphi_{n} + \frac{1}{n} \left[ H(\varphi)(\varphi - \varphi^{*}) + S(\hat{Y}; \varphi^{*}) + \pi(\varphi, \hat{Y}; \varphi^{*}) \right] \]
\[ + \left[ S_{\varphi}(\hat{Y}; \varphi^{*}) - H_{\varphi}(\varphi^{*}) \right] \]
\[ \cdot (\varphi - \varphi^{*}) + \pi(\varphi, \hat{Y}_{n}(\varphi_{n} - \varphi^{*}) + \xi_{n}) \]
\[ \leq \eta \quad \text{and} \quad |\xi_{n}| \leq \eta \quad \text{w.p. } n \geq 1 - \eta_{0}. \]

By modifying the process on a set of probability at most \( \eta_{0} \), we may suppose that (31) holds for all \( n \geq N_{n_{0}} \) and all conditions hold for the modified process. Denote the modified process
by $\varphi_n^0$. The tightness of $\{n^{\gamma/2}\varphi_n^0\}$ will imply the tightness of $\{n^{\gamma/2}\varphi_n\}$. Thus, for the tightness proof, without loss of generality, assume the original process itself $\{\varphi_n\}$ satisfies inequality (31).

Since $H_{\varphi}(\varphi^*)$ is Hurwitz, by virtue of the inverse Liapunov stability theorem, for any symmetric and positive definite matrices $P$ and $Q$ has a unique solution that is symmetric and positive definite. Choose a pair of symmetric and positive-definite matrices $Q$ and $P$ such that $P \geq \lambda Q$ where $\lambda = (\mu_{\text{max}}(P)/\mu_{\text{min}}(Q))$ and $\mu_{\text{max}}(A)$ and $\mu_{\text{min}}(A)$ denote the maximum and minimal eigenvalues of a symmetric and positive-definite matrix $A$, respectively.

Define a Liapunov function by

$$V(\varphi) = (\varphi - \varphi^*)^T Q (\varphi - \varphi^*).$$

Then

$$E_n V(\varphi_{n+1}) - V(\varphi_n) = \frac{2}{\eta^\gamma} (\varphi_n - \varphi^*)^T Q H_{\varphi}(\varphi^*)(\varphi_n - \varphi^*) + O\left(\frac{1}{n^{2\gamma}}\right) |\varphi_n - \varphi^*|^2 |\pi(\varphi_n, \tilde{Y}_n)|$$

$$+ \frac{2}{\eta^\gamma} (\varphi_n - \varphi^*)^T Q S(\tilde{Y}_n; \varphi^*)$$

$$+ \frac{2}{n^{\gamma}} (\varphi_n - \varphi^*)^T Q [S(\tilde{y}_n; \varphi^*) - H_{\varphi}(\varphi^*)] (\varphi_n - \varphi^*)$$

$$+ \frac{2}{n^{\gamma}} (\varphi_n - \varphi^*)^T Q \xi_n$$

$$+ O\left(\frac{1}{n^{2\gamma}}\right) E_n |S(\tilde{y}_n; \varphi_n) + \xi_n|^2.$$ (35)

Given $\eta > 0$, denote $\eta_1$ to be such that $\eta_1 \to 0$ as $\eta \to 0$ and

$$\sup_{n, \varphi_n \in \mathbb{R}^1, |\varphi_n| \leq \eta} \left[|\pi(\varphi_n, \tilde{y}_n)| + |\xi_n|\right] = \eta_1.$$

Define the perturbed Liapunov function by

$$V_n(\varphi) \overset{\text{def}}{=} V(\varphi_n) + \delta V_n(\varphi_n)$$

$$= V(\varphi_n) + 2(\varphi_n - \varphi^*)^T Q H_{\varphi}(\varphi^*)(\varphi_n - \varphi^*)$$

$$+ 2(\varphi_n - \varphi^*)^T Q [P(\varphi_n - \varphi^*)] - \lambda V(\varphi_n)$$

Then in the calculation of $E_n \delta V_{n+1}(\varphi_{n+1}) - \delta V_n(\varphi_n)$, three negative terms cancel that of the terms on the third, the fourth, and the fifth lines of (32). Since we obtain

$$E_n V_{n+1}(\varphi_{n+1}) - V(\varphi_n) \leq -\frac{1}{\eta^\gamma} \lambda V(\varphi_n) + O\left(\frac{1}{n^{2\gamma}}\right) E_n |S(\tilde{y}_n; \varphi_n)|^2$$

$$+ \eta_1 O\left(\frac{1}{n^{\gamma}}\right) |\varphi_n - \varphi^*|^2 + \frac{1}{n^{\gamma}} |\varphi_n - \varphi^*| |E_n \tilde{P}_{n+1}|$$

$$+ E_n |\tilde{P}_{n+1}||O\left(\frac{1}{n^{\gamma}}\right) |\varphi_n - \varphi^*||S(\tilde{y}_n; \varphi_n)|$$

$$+ O\left(\frac{1}{n^{2\gamma}}\right) |S(\tilde{y}_n; \varphi_n)|^2$$

$$+ \frac{1}{n^{\gamma}} |\varphi_n - \varphi^*|^2 |E_n \tilde{P}_{n+1}| + E_n |\tilde{P}_{n+1}|$$

$$\cdot \left[O\left(\frac{1}{n^{\gamma}}\right) |\varphi_n - \varphi^*|^2 \xi_n + O\left(\frac{1}{n^{2\gamma}}\right) |\xi_n|^2 \right].$$ (36)

Taking expectation and using the arguments, detailed computation then leads to

$$E V_{n+1}(\varphi_{n+1}) \leq -\frac{\lambda}{\eta^\gamma} E V(\varphi_n) + \lambda \eta \frac{1}{n^{\gamma}} E |\varphi_n - \varphi^*|^2 + O\left(\frac{1}{n^{2\gamma}}\right)$$

where $\lambda_n \to 0$ as $\eta \to 0$. Recall that $|\varphi_n - \varphi^*| \leq \eta$ for sufficiently small $\eta$. Using (29), $E \delta V_n(\varphi_n) \leq \kappa/n^\gamma$. It follows that for $\lambda_1 < \lambda$

$$E V_{n+1}(\varphi_{n+1}) \leq \left(1 - \frac{\lambda_1}{\eta^\gamma}\right) E V_n(\varphi_n) + O\left(\frac{1}{n^{2\gamma}}\right).$$

Iterating on the above inequality

$$E V_n(\varphi_{n+1}) \leq \kappa \prod_{i=1}^{n} \left(1 - \frac{\lambda_1}{\eta^\gamma}\right) E V_0(\varphi_0)$$

$$+ \kappa \sum_{i=1}^{n} \frac{1}{n^\gamma} \prod_{j=i}^{n} \left(1 - \frac{\lambda_1}{\eta^\gamma}\right) = O\left(\frac{1}{n^{\gamma}}\right).$$

This, in turn, yields that $EV(\varphi_n) \leq \kappa/n^\gamma$ as desired.

Thus, the estimate for $E|\varphi_n - \varphi^*|^2$ is obtained. The estimate for $E|\varphi_n - \varphi^*|^2$ can be obtained similarly with the use of the recursion for $\varphi_n^n$.

Asymptotic Normality: First, we deduce an asymptotic equivalency which indicates that $\sqrt{n}(\varphi_n - \varphi^*)$ has a very simple form. Then the asymptotic normality follows.

Note that the algorithm as a recursion for $\varphi_n$ is

$$\varphi_{n+1} = \varphi_n + \frac{1}{n^{(n+1)}} \sum_{i=1}^{n} S(\tilde{y}_i; \varphi_i).$$

Define $\tilde{\varphi}_n = \varphi_n - \varphi^*$ and $\varphi_n = \tilde{\varphi}_n - \varphi^*$. We then obtain

$$\tilde{\varphi}_{n+1} = \tilde{\varphi}_n + \frac{H_{\varphi}(\varphi^*)}{n^{\gamma}} \varphi_n - \frac{H_{\varphi}(\varphi^*)}{n^{(n+1)}} \tilde{\varphi}_n$$

$$+ \frac{1}{n^{(n+1)}} \sum_{i=1}^{n} S(\tilde{y}_i; \varphi^*) - H_{\varphi}(\varphi_i) + O\left(|\varphi_i|^2\right).$$ (37)
Define a matrix-valued product as
\[ A_{nk} = \begin{cases} 
\prod_{i=k+1}^{n} (1 + H_{\varphi}(\varphi^{*})/i^{\gamma}), & k < n \\
1, & k = n.
\end{cases} \]

Writing down the solution of (34) in its variational form leads to
\[
\sqrt{n} \Phi_{n+1} = \sqrt{n} A_{n0} \Phi_{1} - \sqrt{n} \sum_{k=1}^{n} \frac{1}{k^{\gamma}(k+1)} A_{nk} H_{\varphi}(\varphi^{*}) \Phi_{k} \\
+ \sqrt{n} \sum_{k=1}^{n} \frac{1}{k^{\gamma}(k+1)} A_{nk} \sum_{i=1}^{k} [S(\bar{Y}_{i}; \varphi_{i}) - H(\varphi_{i})] \\
+ \sqrt{n} \sum_{k=1}^{n} \frac{1}{k^{\gamma}(k+1)} A_{nk} \sum_{i=1}^{k} O(|\varphi_{k}|^{2}). \quad (38)
\]

**Lemma 4.3:** Assume the conditions of Theorem 4.2. Then the following assertions hold:

a) As \( n \to \infty \)
\[
\sqrt{n} \Phi_{n+1} = -\frac{H_{\varphi}^{-1}(\varphi^{*})}{\sqrt{n}} \sum_{i=1}^{n} [S(\bar{Y}_{i}; \varphi_{i}) - H(\varphi_{i})] + o(1)
\]
where \( o(1) \to 0 \) in probability as \( n \to \infty \).

b) Define
\[
W^{n}(t) = \frac{1}{\sqrt{n}} \left( \Phi_{nt+1} - \varphi^{*} \right), 
\]for \( t \in [0, 1] \).

Then
\[
W^{n}(t) = -\frac{H_{\varphi}(\varphi^{*})}{\sqrt{n}} \sum_{i=1}^{nt} [S(\bar{Y}_{i}; \varphi_{i}) - H(\varphi_{i})] + o(1)
\]
where \( o(1) \to 0 \) in probability uniformly in \( t \).

**Proof:** We prove only the first assertion. The second one can be proved analogously. Examine (35) term by term. Let us begin with the last term. Using Theorem 4.2 and the boundedness of \( \{\varphi_{n}\} \)
\[
E \left| \sqrt{n} \sum_{k=1}^{n} \frac{1}{k^{\gamma}(k+1)} A_{nk} \sum_{i=1}^{k} \varphi_{i} \right| 
\leq \kappa \sqrt{n} \sum_{k=1}^{n} \frac{1}{k^{\gamma}} |A_{nk}| O(1) 
\]
\[
\leq \kappa \sqrt{n} O(n^{-\gamma}) \to 0, \quad \text{as} \quad n \to \infty.
\]
We also have (by using Theorem 4.2),
\[
E \left| \sqrt{n} A_{n0} \Phi_{1} \right| \leq \kappa \sqrt{n} |A_{n0}| E |\varphi_{1}| \to 0, \quad \text{as} \quad n \to \infty
\]
and
\[
E \left| \sqrt{n} \sum_{k=1}^{n} \frac{1}{k^{\gamma}(k+1)} A_{nk} H_{\varphi}(\varphi^{*}) \Phi_{k} \right| 
\leq \kappa \sqrt{n} \sum_{k=1}^{n} \frac{1}{k^{\gamma}(k+1)} |A_{nk}| |H_{\varphi}(\varphi^{*})| E |\varphi_{k}| \to 0, \quad \text{as} \quad n \to \infty.
\]

For the term on the second line of (35), using a partial summation
\[
\sqrt{n} \sum_{k=1}^{n} \frac{1}{k^{\gamma}k} A_{nk} \sum_{i=1}^{k} \left( S(\bar{Y}_{i}; \varphi_{i}) - H(\varphi_{i}) \right) 
\]
\[
= \left[ \sum_{k=1}^{n} \frac{1}{k^{\gamma}k} A_{nk} \right] \left[ \frac{1}{\sqrt{n}} \sum_{i=1}^{n} \left( S(\bar{Y}_{i}; \varphi_{i}) - H(\varphi_{i}) \right) \right] 
\]
\[
+ \sqrt{n} \sum_{k=1}^{n-1} \left[ \sum_{i=1}^{k} \frac{1}{i^{\gamma}} A_{ni} \right] \frac{1}{k} \sum_{i=1}^{k} \left( S(\bar{Y}_{i}; \varphi_{i}) - H(\varphi_{i}) \right) 
\]
\[- \frac{1}{k+1} \sum_{i=1}^{k+1} S(\bar{Y}_{i}; \varphi_{i}) - H(\varphi_{i}) \right] .
\]
Since
\[
\sum_{k=1}^{n} \frac{1}{k^{\gamma}k} A_{nk} = -H_{\varphi}^{-1}(\varphi^{*}) (I - A_{n0})
\]
\[
\left[ \sum_{k=1}^{n} \frac{1}{k^{\gamma}k} A_{nk} \right] \left[ \frac{1}{\sqrt{n}} \sum_{i=1}^{n} \left( S(\bar{Y}_{i}; \varphi_{i}) - H(\varphi_{i}) \right) \right]
\]
\[- \frac{1}{\sqrt{n}} \sum_{i=1}^{n} \left( S(\bar{Y}_{i}; \varphi_{i}) - H(\varphi_{i}) \right) + o(1)
\]
where \( o(1) \to 0 \) in probability as \( n \to \infty \). Similarly, we have
\[
\sqrt{n} \sum_{k=1}^{n-1} \left[ \sum_{i=1}^{k} \frac{1}{i^{\gamma}} A_{ni} \right] 
\]
\[- \frac{1}{k+1} \sum_{i=1}^{k+1} S(\bar{Y}_{i}; \varphi_{i}) - H(\varphi_{i}) \right] 
\]
\[= \sqrt{n} H_{\varphi}^{-1}(\varphi^{*}) \sum_{k=1}^{n-1} (A_{nk} - A_{n0})
\]
\[- \frac{1}{k+1} \sum_{i=1}^{k+1} S(\bar{Y}_{i}; \varphi_{i}) - H(\varphi_{i}) \right] 
\]
\[\to 0 \quad \text{in probability.}
\]
Thus, asymptotically the term on the second line of (35) is given by
\[
-\frac{H_{\varphi}^{-1}(\varphi^{*})}{\sqrt{n}} \sum_{i=1}^{n} \left( S(\bar{Y}_{i}; \varphi_{i}) - H(\varphi_{i}) \right) + o(1).
\]

**Theorem 4.4:** Under the conditions of Lemma 4.3, \( W^{n}(\cdot) \)
converges weakly to a Brownian motion with the optimal covariance \( H_{\varphi}^{-1}(\varphi^{*}) \Sigma (H_{\varphi}^{-1}(\varphi^{*}))' \), where \( \Sigma \) is given by (21).

**Proof:** By virtue of the argument as in [24], [25], it can be shown that \( (1/\sqrt{n}) \sum_{i=1}^{nt} \bar{S}_{i} \) converges weakly to a Brownian motion. Owing to \( \varphi_{n} \to \varphi^{*} \) and the continuity of \( H(\cdot) \), \( H(\varphi_{n}) \to H(\varphi^{*}) = 0 \). Likewise, it follows from A2) and the
boundedness of the iterates, \( E[S(\tilde{Y}_n; \varphi_n) - S(\tilde{Y}_n; \varphi^*)] \to 0 \) as \( n \to \infty \). Therefore, the covariance of the resulting Brownian motion

\[
\lim_{n \to \infty} \frac{1}{n} \sum_{i=1}^{\lfloor nt \rfloor} \sum_{j=1}^{\lfloor nt \rfloor} \cdot E \left[ S(\tilde{Y}_i; \varphi_i) - H(\varphi_i) \right] \left[ S(\tilde{Y}_j; \varphi_j) - H(\varphi_j) \right]' = \lim_{n \to \infty} \frac{1}{n} \sum_{i=1}^{\lfloor nt \rfloor} \sum_{j=1}^{\lfloor nt \rfloor} ES(\tilde{Y}_i; \varphi^*) S(\tilde{Y}_j; \varphi^*) = t \Sigma,
\]

Finally, by Slutsky’s theorem, the desired result follows. \( \square \)

**Remark 4.5:** An interesting problem to study concerns the rates of convergence taking into consideration the computational budget devoted to the underlying computation. Such problems were dealt with in [26]; see also the subsequent generalization in [41].

**V. Constant Step-Size Tracking Algorithms**

In this section, we study algorithms with a constant step size, i.e., \( \varepsilon_n = \varepsilon > 0 \). These algorithms can be used to track AR model with Markov regime whose parameters vary slowly with time. The pertinent notion of convergence is in the sense of weak convergence (see [14], [23], [25]). The algorithm of interest is

\[
\varphi^e_{n+1} = \Pi_G \left( \varphi^e_n + \varepsilon S(\tilde{Y}_n; \varphi^e_n) \right).
\]

Again a constraint set is used for the estimation scheme. In the subsequent development, to save some notation, we often write \( \varphi_n \) in lieu of \( \varphi^e_n \) for simplicity, and retain the \( \varepsilon \) dependence whenever necessary. To proceed, we write the recursion as

\[
\varphi_{n+1} = \varphi_n + \varepsilon S(\tilde{Y}_n; \varphi_n) + \varepsilon M_n
\]

where \( M_n \) is the reflection or projection term.

Define the piecewise-constant interpolations by

\[
\varphi^e(t) = \begin{cases} 
\varphi^e_0, & \text{for } t < 0 \\
\varphi^e_n, & \text{for } t \geq 0 \text{ and } t \in [n \varepsilon, n \varepsilon + \varepsilon)
\end{cases}
\]

and

\[
M^e(t) = \begin{cases} 
0, & \text{for } t < 0 \\
\lfloor t/\varepsilon \rfloor - \sum_{i=0}^{\lfloor t/\varepsilon \rfloor - 1} M_i^e, & \text{for } t \geq 0
\end{cases}
\]

where \( \lfloor t/\varepsilon \rfloor \) is the integer part of \( t/\varepsilon \).

**Theorem 5.1:** Suppose that \( \varphi^e_0 \) converges weakly to \( \varphi_0 \) as \( \varepsilon \to 0 \), that for each \( \tilde{M} > 0 \), the stationary sequence \( \{S(\tilde{Y}_i; \varphi) : |\varphi| \leq \tilde{M} \} \) is uniformly integrable, that \( S(\tilde{Y}_i; \cdot) \) is continuous for each \( \tilde{Y}_i \), that \( ES(\tilde{Y}_i; \varphi) = H(\varphi) \) and \( H(\varphi) \) is continuous, and that for each \( \varphi \) and each \( \mu \), as \( n \to \infty \)

\[
1 \sum_{i=1}^{n+1} \sum_{\mu<i} E_\mu S(\tilde{Y}_i; \varphi) \to H(\varphi) \text{ in probability.}
\]

Then \( \varphi^e(\cdot) \) converges weakly to \( \varphi(\cdot) \) that is a solution of the ODE (15), provided the ODE has a unique solution for each initial condition.

Let \( \{\xi_f \} \) be a sequence of real numbers such that \( \varepsilon \xi_f^2 \to \infty \) as \( \varepsilon \to 0 \). Then for almost all \( \omega \), \( \varphi(\omega, \cdot) \) the limit of \( \varphi(\varepsilon \xi_f + \cdot) \) belongs to an invariant set of (15). If \( L_G \) is asymptotically stable, then the invariant set is in \( L_G \). In addition, suppose that \( \varphi^* \in G^* \) is the unique point such that \( H(\varphi) = 0 \). Then \( \theta^e(\varepsilon \xi_f + \cdot) \) converges weakly to \( \varphi^* \).

**Remark 5.2:** Note that compared to the w.p. 1 convergence, the conditions here are much weaker. In fact, only weak ergodicity in the form of (37) is needed. If the stronger geometric ergodicity holds (see the sufficient conditions given in Section III), then (37) is automatically satisfied. The proof of the theorem essentially follows from the development in [25, Ch. 8]. Owing to the projection, \( \{\varphi^e_n \} \) is bounded, so it is tight. Then all the conditions in [25, Theorem 8.2.2] are satisfied. The assertion follows. To proceed, we state a rate of convergence result below.

**Theorem 5.3:** Suppose that the conditions of Theorem 5.1 hold, that there is a nondecreasing sequence of real numbers \( \{\tilde{t}_e \} \) satisfying \( \tilde{t}_e \to \infty \) as \( \varepsilon \to 0 \) such that \( \varphi^e(\tilde{t}_e + \cdot) \) converges weakly to the process with constant value \( \varphi^* \in G^0 \), that there exists \( \tilde{t}_e \geq \tilde{t}_e \) such that \( ((\varphi^e_{n+1+[\tilde{t}_e/\varepsilon]} - \varphi^*)/\varepsilon) \) is tight, and that \( \text{(A5), (A7) a), and (A8) are satisfied. Define

\[
U^e_n = \frac{\varphi^e_{\lfloor t/\varepsilon \rfloor + n} - \varphi^*}{\varepsilon^2}
\]

\[
U^e(t) = u_n, \quad \text{for } t \in [n \varepsilon, n \varepsilon + \varepsilon)
\]

\[
W^e(t) = \sqrt{\frac{\lfloor t/\varepsilon \rfloor + [\lfloor t/\varepsilon \rfloor - 1]}{\varepsilon}} S(\tilde{Y}_i; \varphi^*), \quad \text{for } t \geq 0.
\]

Then \( (U^e(\cdot), W^e(\cdot)) \) converges weakly in \( D^{2r(r+1)}(0, \infty) \) to \( (U(\cdot), W(\cdot)) \), and

\[
dU = H_2(\varphi^*) \text{d}t + dW
\]

where \( W(\cdot) \) is a Brownian motion having covariance \( \Sigma t \) with \( \Sigma \) given by (21).

**VI. Numerical Examples**

We refer the reader to [10] for several numerical examples that illustrate the performance of the RMLE and the recursive expectation–maximization (EM) algorithm for HMM parameter estimation. Also [11] presents several numerical examples that illustrate the performance of the recursive EM algorithm in estimating AR processes with Markov regime. (The recursive EM algorithm is identical to the RMLE algorithm apart from the fact that it uses a different step size). Our aim here is to illustrate the performance of the RMLE algorithm for parameter estimation of AR models with Markov regime in two numerical examples. In [21], off-line ML parameter estimation was performed on these two numerical examples.

**Example 1: Linear AR Model With Gaussian Noise:** Consider a second-order (\( d = 2 \)) AR model of the type

\[
Y_n = -b_{n-1} Y_{n-1} - b_{n-2} Y_{n-2} + \sigma_{X_n} e_n.
\]

Let \( r = 2, n = 20000 \), and let the true parameters be

\[
A^0 = \begin{bmatrix} 0.95 & 0.05 \\ 0.05 & 0.95 \end{bmatrix}, \quad I^0 = \begin{bmatrix} 0.5 & 0.5 \\ -0.5 & 0.8 \end{bmatrix}, \quad \sigma^0 = \begin{bmatrix} 0.3 \\ 0.8 \end{bmatrix}.
\]
found that for the algorithms with iterate averaging and step autoregression of the type algorithm was initialized at numerically ill-conditioned for some sample paths. Averaging algorithm was run initialized at Table I gives the sample means and standard deviations (in Table I

The parameter vector can be taken as

$$\varphi = (a_{11}, a_{22}, b_{11}, b_{21}, b_{22}, \sigma_1, \sigma_2)$$

i.e., $p = 8$. Fifty independent sample paths based on the above model were generated. For each sample path, the RMLE algorithm was run initialized at

$$\varphi_0 = [0.5, 0.5, 0.0, 0.0, 0.0, 0.0, 0.1, 0.2].$$

Table I gives the sample means and standard deviations (in parenthesis) over these 50 replications for various step sizes with and without averaging.

**Comments:** The best results were obtained for $\gamma = 0.7$. We found that for the algorithms with iterate averaging and step sizes of the form $k^\gamma$, $\gamma < 0.6$, the RMLE algorithm became numerically ill-conditioned for some sample paths. Averaging of both observations and iterates appears to have better transient characteristics.

**Fixed-Step Size Tracking:** The following time-varying linear AR model was simulated:

$$A^0 = \begin{bmatrix} 0.95 & 0.05 & 0.05 \\ 0.05 & 0.95 & 0.05 \\ 0.05 & 0.05 & 0.95 \end{bmatrix}, \quad B^0 = \begin{bmatrix} 0.5 & 0.5 \\ -0.5 & 0.8 \\ 0.5 & -0.5 \end{bmatrix}, \quad \sigma^0 = \begin{bmatrix} 0.3 \\ 0.8 \end{bmatrix}$$

$n < 25000$

$$A^0 = \begin{bmatrix} 0.6 & 0.4 \\ 0.2 & 0.8 \\ 0.4 & 0.2 \end{bmatrix}, \quad B^0 = \begin{bmatrix} 0.1 & -0.4 \\ -0.9 & 0.2 \\ -0.4 & 0.1 \end{bmatrix}, \quad \sigma^0 = \begin{bmatrix} 0.1 \\ 0.3 \end{bmatrix}$$

$25000 \leq n \leq 50000$

Fig. 1 illustrates the tracking performance of the RMLE algorithm for step sizes of $\epsilon = 10^{-3}$ and $\epsilon = 3 \times 10^{-3}$. The RMLE algorithm was initialized at

$$\varphi_0 = [0.5, 0.5, 0.0, 0.0, 0.0, 0.0, 0.1, 0.2].$$

**Example 2: Nonlinear Autoregression With Gaussian Noise:** Here we consider a first-order ($d = 1$) nonlinear autoregression of the type

$$Y_n = \exp(-b_{11} Y_{n-1}^2) + \sigma_{1} e_n$$

where $\{e_k\}$ is an i.i.d. sequence of standard normal random variables.

Let $r = 2$, $n = 40000$, and the true parameters be

$$A^0 = \begin{bmatrix} 0.9 & 0.1 \\ 0.1 & 0.9 \end{bmatrix}, \quad B^0 = \begin{bmatrix} 0.4 \\ 0.9 \end{bmatrix}, \quad \sigma^0 = \begin{bmatrix} 0.1 \\ 0.1 \end{bmatrix}.$$  

The initial parameter estimate

$$\varphi_0 = (a_{11}, a_{22}, b_{11}(1), b_{21}(1), \sigma_1(1), \sigma_2(1))$$

was chosen as $(0.5, 0.5, 0.7, 0.3, 0.5, 0.5)$.

Table II gives the sample means and standard deviations (in parenthesis) over these 50 replications for various step sizes with and without averaging.

Here $b_{11}$ is more difficult to estimate than $b_{12}$, which might be explained by the inequality $b_{2} > b_{1}$; the exponential function $\exp(-b_{11}^2)$ decays faster and is thus smaller in comparison to the noise for $i = 2$.

By conducting several numerical experiments for the above nonlinear autoregressive model we noticed that the convergence of the RMLE algorithm was sensitive to initialization of $B_0$. The closer the initial value $b_{11}(1)$ was picked to $b_{21}(1)$, the slower the initial convergence of the algorithm. For initializations

$$b_{11}(1) - b_{21}(1) > 0.05$$

and in the region $0 < b_{11}(1) < 2$ and $0 < b_{21}(1) < 2$ the algorithm converged to the true parameter values within 40000 time points.

**Fixed-Step Size Tracking:** The following time-varying version of the above nonlinear AR model was simulated:

$$A^0 = \begin{bmatrix} 0.90 & 0.10 \\ 0.10 & 0.90 \end{bmatrix}, \quad B^0 = \begin{bmatrix} 0.4 \\ 0.9 \end{bmatrix}, \quad \sigma^0 = \begin{bmatrix} 0.1 \\ 0.1 \end{bmatrix}$$

$n < 25000$

$$A^0 = \begin{bmatrix} 0.6 & 0.4 \\ 0.6 & 0.4 \end{bmatrix}, \quad B^0 = \begin{bmatrix} 0.2 \\ 0.7 \end{bmatrix}, \quad \sigma^0 = \begin{bmatrix} 0.3 \\ 0.8 \end{bmatrix}$$

$25000 \leq n \leq 60000$.

Fig. 1. Tracking performance of RMLE for linear AR model. Step sizes are $\epsilon = 10^{-3}$ and $\epsilon = 3 \times 10^{-3}$, respectively. The parameters are specified in Section VI.

Fig. 2 illustrates the tracking performance of the RMLE algorithm for step sizes of

$\epsilon = 10^{-3}$ and $\epsilon = 3 \times 10^{-3}$.

The RMLE algorithm was initialized at

$\varphi_0 = [0.5, 0.5, 0.0, 0.0, 0.0, 0.0, 0.1, 0.2]$.

VII. CONCLUSION AND EXTENSIONS

We have focused on developing asymptotic properties of recursive estimators of stochastic approximation type for hidden Markov estimation. Convergence and rate of convergence results are obtained for both decreasing and constant step-size algorithms. In addition, we have demonstrated that algorithms
with averaging in both iterates and observations are asymptotically optimal in the sense they have the best scaling factor and achieve the “smallest possible” variances. For future research, it is both interesting and important to design continuous-time recursive estimators for hidden Markov estimation. It will be of interest from a practical point of view to consider problems under simulation based setting. Recent efforts in this direction can be found in the work of Ho and Cao [18], Konda and Borkar [8], L’Ecuyer and Yin [26], Tang, L’Ecuyer, and Chen [40] among others.
ACKNOWLEDGMENT

The authors gratefully thank the reviewers and the Associated Editor for the detailed comments and suggestions, which lead to much improvement of the paper.
